The social role of objects goes beyond representation and identities (Cipolla 2017; Creese 2017; van Oeyen and Pitts 2017). Foreign objects were not simply exported to Nubia. Contrarily, "mobile standardized objects in a wider connected milieu" reached "multiple communities rather than just a single locality" (Pitts 2019: 14). Locally and contextually, foreign objects performed roles which helped creating and reinforcing colonial social relations. In this way, communities consumed and used objects in varied fashions; their choices regarding which objects to include in their burial assemblages, or which sets of meanings to emphasize through material culture changed considerably. These choices, on the other hand, were influenced by a social context which limited the use of certain categories of objects, as the access to these objects would require power and the ability to cross the boundaries of social spaces by those individuals who desired these items. This context created various "burial communities" within New Kingdom Nubia, which consumed differently and produced different entanglements according to their possibilities and limitations to consume.

Näser (2017) recently applied the concept of "burial communities" to objects from the Aniba cemetery. The concept derives from Lave and Wenger's concept of "communities of practice" (Lave and Wenger 1991). It emphasizes collective or social learning practices that result in strategies. The recognition of different burial communities consists of a first step towards the awareness of the internal diversity that characterized cultural interactions in New Kingdom Nubia, contrarily to previous approaches based on cultural entanglement which considered Nubia as a homogenous cultural entity that regularly interacted with the Egyptian colonizers.

Broadly speaking, the same categories of objects appear at Aniba, Sai, Soleb, and Fadrus (Table 4). Other sites could have been included in the following discussion, but, on the one hand, Aniba, Sai, and Soleb can be considered as representing "elite" ideals and practices regarding death; on the other hand, Fadrus represents a "non-elite" burial ground. Therefore, the following discussion of the material culture of these sites takes into account possible distinctions between "elites" and "non-elites" (for discussion of terminology, see Lemos 2017: 124–125).

Amulets/pendants, coffins, earrings, kohl jars, masks, mirrors, necklaces/beads, rings, and scarabs are common to all cemeteries. Other objects are shared between most of the sites, such as toiletry equipment, jewelry, and weaponry. On the one hand, objects that are common at various cemeteries represent the broad social context of the colonization of Nubia, when Egyptian-style objects became widely available and their presence increased at cemeteries and settlements. On the other hand, the categories of objects present only at a few sites, or those objects which tend to concentrate at elite cemeteries (e.g., shabtis and heart scarabs), represent the internal social and cultural diversity within colonial Nubia.

Visually representing the distribution of objects at cemeteries is a helpful tool for us to understand the internal diversity of New Kingdom Nubia. In a context of apparent standardization, given by the widespread presence of Egyptian-style objects throughout the colony, some preferences can be identified at certain sites, as well as differences in the overall quantity of the categories of objects which appear at various sites.

At Aniba (Graph 1), shabtis are the most representative objects, comprising 1062 items and distributed across 51 tombs (more than 32% of the total number of tombs). In absolute numbers, shabtis represent the most popular category of object at Aniba. However, based on the number of tombs in which they were excavated, shabtis consist of the second most chosen object at the site. Scarabs are the most widespread objects, found in 68 tombs – a pattern which is also found elsewhere. Nonceramic vessels, pendants, and rings also represent popular choices at Aniba. Rings are very rare at other sites and might have a closer relationship with elite groups. Even though

Material Culture and Colonization in Ancient Nubia: Evidence from the New Kingdom Cemeteries, Graph 1 Distribution of objects at Aniba[5]

the number and distribution of heart scarabs is low, if compared to other types of objects, their presence at the site is the highest when compared to Sai and Soleb. These objects were very restricted in New Kingdom Nubia, even among the elites.

At Sai (Graph 2), shabtis are also among the preferred types of objects. Pendants and scarabs were equally popular, distributed across 60% and 56% of the tombs, respectively, although the absolute number of pendants is higher. Earrings

[5]The distribution graph for Aniba does not include shabtis. The high number of shabtis at the site makes it difficult to visualize how the other categories behave. The numbers and distribution of shabtis are discussed in the text.

Material Culture and Colonization in Ancient Nubia: Evidence from the New Kingdom Cemeteries, Graph 2 Distribution of objects at Sai

represent another preferred object, a pattern which is not found at Aniba. This might indicate alternative ideals regarding the display of identities and power among elite groups buried at Aniba, Sai, and Soleb (Graph 3), where earrings were also common. Most of the earrings found at New Kingdom Nubian cemeteries are of penannular type and could be made of materials such as bone and ivory, which are considered Nubian identity markers. However, most of the earrings at Sai are made of carnelian and red jasper (Minault-Goult and Thill 2012: plate 121). Heart scarabs were also found at Sai, which suggests that the site housed elite individuals able to consume very restricted objects, most of which were imported. This would suggest that elite groups consuming restricted imported items desired to create affinities with the Egyptian culture, but, at Sai, a greater display of connections with Nubian traditions through penannular earrings was also permitted.

The distribution of objects at Soleb is highly similar to the pattern identified at Sai, but different in comparison with Aniba. Earrings represent the most popular objects, both in terms of absolute numbers and distribution across various tombs. At Soleb, 53% of the earrings were made of jasper, but 38% were made of shell (or another similar material such as bone). This would represent a clearer affinity with local Nubian cultures, which made extensive use of materials such as shell and bone to manufacture jewelry items. However, at the same time, high-quality shabtis and heart scarabs were also found at Soleb, similarly to Aniba and Sai. Pendants and scarabs equally comprise well-liked choices.

The distribution pattern at Fadrus differs considerably from Aniba, Sai, and Soleb (Graph 4). This might be attributed to differences between elites and non-elites. Fadrus houses the most varied set of objects among the four compared sites. The preferred types of objects also differ if

Material Culture and Colonization in Ancient Nubia: Evidence from the New Kingdom Cemeteries, Graph 3 Distribution of objects at Soleb

Material Culture and Colonization in Ancient Nubia: Evidence from the New Kingdom Cemeteries, Graph 4 Distribution of objects at Fadrus

compared to Aniba, Sai, and Soleb. No shabtis have been found at Fadrus, which relates to the fact that the site is a non-elite cemetery, while shabtis tend to be restricted to elite sites. However, as an exception, one heart scarab was found at the site. Scarabs and pendants are also very common types of objects, as well as earrings. The high percentage of kohl jars suggest that different ideals were circulating among the populations buried at Fadrus. In contrast, these objects were not found at Aniba, Sai, and Soleb at such high rates, which again might be related to differences between elites and non-elites. The high frequency of coffins at Fadrus is probably related to the fact that most of the burials were found intact, which is not the case at other sites.

As mentioned, standardization towards an Egyptian model is based on a variety of objects shared across cemeteries. However, tools such as grindstones, hammerstones, staffs, etc. tend to appear only at Fadrus, while shabtis and heart scarabs tend to appear at the larger administrative centers where elite officials resided. This would be a further indication of the social role of objects towards the creation of local hierarchies. While the non-elite population at Fadrus would have performed tasks for which a whole set of different tools were required, elite individuals at Aniba, Sai, and Soleb were able to possess more restricted funerary objects within their tombs, therefore being able to use entanglements in their favor.

Material culture meant different things for different communities. The distribution and frequency of objects at Aniba, Sai, Soleb, and Fadrus point towards the existence of local, distinctive ideals regarding object choices. This suggests that different ideals and cultural affinities were circulating and being negotiated within New Kingdom Nubia. The communities at Aniba, Sai, and Soleb shared characteristics such as the choice for shabtis and heart scarabs, objects which probably marked social differences. However, the communities at Sai and Soleb differed from the one at Aniba, as they opened more space for affinities with Nubian patterns to be created through penanular earrings. On the other hand, at Fadrus, people disposed of a more varied set of objects (mostly objects used in daily life activities such as scarab seals, which could become mortuary offerings), but their choices were more limited than the communities at Aniba, Sai, and Soleb. At these sites, individuals were able to consume restricted objects such as shabtis and heart scarabs, which were either imported or commissioned in a local workshop for a price, which was likely only affordable to certain individuals.

Different burial communities point to the existence of different ideals of death and dying, but also conceptions of society and culture. These different views were grounded on various preferences related to the practice of dying, as well as on diverse demands for goods, including objects especially manufactured for the tomb such as shabtis, and objects that *become* mortuary items such as jewelry. However, a diversity of conceptions and demands, which result in different types and degrees of entanglement, took place in a context where most of the available items looked Egyptian in style. Such diversity results from the fact that the global phenomenon represented by Egyptian-style material culture reached not only distinct regions within Nubia but also different social groups (Williams 2018: 106). Therefore, in a context of aprioristic standardization that grounded previous emphases on Egyptianization, the internal diversity of Nubia created a complex setting in which more than two cultural entities (e.g., "Egypt" and "Nubia") interacted and produced entanglements. Rather, the foreign ("Egypt") interacted with various versions of Nubia, which carried different social relationships of power, hierarchy, and probably different worldviews. This perspective goes beyond the long-emphasized distinction between Wawat and Kush (Lower and Upper Nubia), which is mainly based on how the ancient Egyptians politically divided their Nubian colony. Rather, the perception of various "Nubias" favors a variety of social and cultural groups and regions, with different beliefs and practices, which expressed their complex set of social relations through their local (re) creations of global/colonial material patterns flowing through the New Kingdom Egyptian empire.

Conclusion and Future Steps

The different distributions of objects and varied emphases given to grave goods are expression of specific burial communities, the existence of which suggests that colonial objects fulfilled local roles in New Kingdom Nubia, rather than representing acculturation and uniformity. This context of internal diversity suggests that entanglements were not as universally available in situations of cultural contact as previously thought. Situations of cultural contact include the consumption and use of Egyptian-style grave goods. The differences in the distribution of objects not only reflect regional preferences, but also restrictions and limitations in the consumption of certain objects; e.g., shabtis and heart scarabs, which were generally restricted in New Kingdom Nubia, and concentrate in elite cemeteries such as Aniba, Sai, and Soleb.

Future postcolonial research is needed in order to shed more light onto the internal diversity of Nubia, underlying the way entanglements took place. A postcolonial approach to colonial Nubia needs to emphasize more than indigenous agency and their role in negotiations of identity through material culture as a whole. Instead, in order for us to fully understand lived experiences in New Kingdom Nubia, future research needs to consider local complexity, social relationships of power, and material possibilities and limitations in the colony. Therefore, topics such as local production and distribution of goods (both imported and locally produced) need to be further investigated, as well as the specific social roles undertaken by objects in contexts of interaction.

State of Knowledge and Current Debates

Introduction

In the 1970s, while strongly influenced by a certain interpretation of oriental mysticism, the former Beatle George Harrison released the album Living in the Material World (1973). Imbued with the sounds of sitars, the songs were presented as musical alternatives to the Western way of life, particularly the US capitalist variety. Barely 10 years later, the theme of the material world returned to the music scene. Madonna's rendition lacked Harrison's orientalism (2003), declaring more complacently that "you know that we are living in a material world" (1985). To continue with our musical references, Pink Floyd's rock opera invoked a schoolboy choir against "dark sarcasm in the classroom" as, ultimately, they didn't "need no education."

The assertion that we live in a material world is no novelty to either the world of art or academia. Interpretations of the different sets of meanings resulting from these relations, however, are varied and can be construed from different perspectives. Among them we are concerned with how these sets of relations negotiate learning relations and the constitution of social subjects through materiality. The 1970s and 1980s marked a true conceptual turn in both archaeology and education. Our intention is to briefly outline a panorama of such a conceptual turn, as a guide to our present understanding of the partnership between these expressions of human activity.

Material culture is a constant presence in human life. We are born, grow up, and die interacting within diverse constellations of materiality, devised for different purposes: these are the structures, objects, and modifications which make up our leisure, work, and dwelling spaces among other countless possibilities. Material culture, being everything that is made or modified by human beings and that makes up humanity's day-to-day experiences, is therefore independent from time and even space.

One of the roles of this materiality is the transmission of knowledge, whether the result of a learning process – e.g., when making a tool – or by shaping the existing models of education as in the spatial layout of a classroom. We understand education as a learning process, a flux of knowledge in which the elders have a duty to cultivate the immature while guaranteeing their right to "shake up and question everything that is enshrined in the name of what is yet to come" (Brandão 2007).

Historic Panorama

If we now move away from the world of music and focus on the academic world, an example of a sharp analyst of the multiple meanings of material culture can be found in the British archaeologist Julian Thomas. Thomas proposes an understanding of the changes in the way material culture has been conceived as a key to the changing relations between people and the varied manifestations of materiality. Starting with the ideas of materiality of Aristotle, through to medieval scholastics and present-day philosophers, Thomas constructs an overview of the world of ideas and its effects and

relationships with the constructions of the material world (Thomas 2004, 202–250).

A second route of inquiry, still within the realm of philosophy but from a perspective which is closer to the history of science, is to reflect on the changing conceptions of material culture within the very field of archaeological science. This choice can be understood based on the authority exerted by archaeological discourses over analyses of material culture throughout the nineteenth and twentieth centuries. As part of a process of constituting and consolidating sciences, history was granted dominion over the analyses of written texts, anthropology dealt preferentially with certain specific cultures, and archaeology remained in charge of ordering, describing, and explaining what we call materiality. Therefore, the underlying question for this second route of inquiry would be how archaeology – perceived as the realm of material culture – understands its own object of study.

It must be highlighted, however, that the very basis of archaeological science allocated the materiality that archaeologists ought to study to past times. Therefore, the science that studied the human past was named archaeology (in Greek, "knowledge of the origins" or "account of things old" (Funari 2003, 10)). Although this definition was outlined throughout the nineteenth century, a significant proportion of scholars define their area as aiming to understand past human times through the analysis of material artifacts. In a recent edition of the book, *Archaeology: Theories, Methods, and Practice* (2008), British archaeologists Colin Renfrew and Paul Bahn present archaeology as:

> Archaeology is the 'past tense of cultural anthropology'. Whereas cultural anthropologists will often base their conclusions on the experience of actually living within contemporary communities, archaeologists study past humans and societies primarily through their material remains – the buildings, tools, and other artifacts that constitute what is known as the material culture left over from former societies. (Renfrew and Bahn 2008, 12)

Archaeology, as presented by Renfrew and Bahn, is constructed from the context of cultural anthropology. With its focus upon the past, the discipline turns material culture into a gateway into human history. Objects are subject to rescue and reconstruction and apt to reveal certain past events or mechanisms of past cultures. This perception of material culture as revealing is only plausible within a certain theoretical discourse about archaeology. Still, as we stated above, it is not the only way to understand materiality or even archaeological science.

Although material culture is enmeshed in human history, it was only in the nineteenth century that it was born as a concept within the studies of prehistory. The French geologist Boucher de Perthes was among the first to use the concept to analyze objects produced by humans during prehistory in his works *Antiquités celtiques et antédiluviennes* (1847) and *De l'homme antédiluvien* (1860). In his analyses, material culture enabled him to make assertions about a human past which had remained unrecorded in writing.

In over 150 years of existence, the term, which has become central to archaeological studies, has been given many different meanings. Archaeological practices of the cultural-historic strand, with their strong nationalist heritage, understood material culture as specific evidence of what humans built and therefore as artifacts. From such vestiges we can elucidate the way certain cultures work. Culture, in this view, is defined as the sum total of all ideas, activities, and materials that characterize the nature of a certain human group (Jones 1997, 17). It would therefore constitute a social legacy of certain shared traditions, institutions, and ways of life, among other elements (Childe 1974).

Within the cultural-historic theoretical universe, artifacts are configured as cultural indicators. Gordon Childe, the Australian archaeologist who laid the foundations of this theory, asserts that artifacts, through the knowledge they allow, are formative of cultures in an archaeological format. It is through the analysis of archaeological culture that one could understand, for example, how:

> (. . .) even in prehistoric times barbarian European societies behaved in a distinctively European way, very vaguely anticipating the contrast which over the past thousand years became flagrant, with African and Asian societies. (Childe 1974, 13)

Within an imperialist mind-set and context, Childe puts forth that artifact assemblages would bear the characteristics of the cultures where they are produced. Therefore, even prehistoric Europeans would have been "superior" to the prehistoric men of Africa and Asia, as they were, after all, already European. A direct correspondence is established between a presupposed cultural group and the sets of materiality produced by it.

Whereas the continuators of the cultural-historic traditions perceived archaeological cultures as bearing explicit and therefore incontrovertible truths, Childe warned his readers:

> The reader must understand the hypothetical character of most archaeological conclusions. We can only ask for him to accept the most likely and most generally admitted deductions although these are still only probable. It is to prevent boredom that question marks are omitted, which otherwise might as well accompany most assertions. (Childe 1974, 19)

Despite the warnings about the hypothetical character of material culture, artifacts were still understood as objective providers of "correct data" about certain cultures in several theoretical quarters.

Processual archaeology, as inaugurated by the work *Method and Theory in American Archaeology* (1958), by the archaeologists Gordon R. Willey and Philip Phillips, questioned the effectiveness of cultural-historic studies and proposed new analyses that would focus on understanding the uses of artifacts by human beings. According to Phillips and Willey, cultural-historic archaeology had delved into the artifact form and the development of grand timelines which afforded little information about the actual cultures which had produced the artifacts under scrutiny.

Influenced by theories of cultural evolution and in an open dialogue with cultural ecology, processual archaeologists opened new lines of inquiry into how certain cultures lived and used their artifacts. In this new view, archaeology became a science without boundaries. According to the French anthropologist and archaeologist André Leroi-Gourhan, material culture and the objectivity which it granted to archaeology allowed the discipline to surpass spatial and chronological boundaries and elaborate syntheses of the general and the particular in reconstructing the objects studied (Leroi-Gourhan 1945).

The access to certain cultures that was enabled by this specific way of recording, as well as its objectivity, began to be challenged, particularly from the 1980s onward, with the birth of post-processual archaeology and the strengthening of postmodernist theories.

The humanities in general and archaeology in particular sought to redefine the concept of culture and the objectivity of the researcher. In this new light, the idea of identifying cultures through archaeological artifacts as espoused by both the cultural-historic and the processual trend became a harder equation to solve.

The difficulties met when defining cultural boundaries among human groups would stem from the sheer impossibility of ascribing clear-cut identities to groups or even individual people. In this scope identity is understood as a series of fluid processes of constructs that answer such questions as "Who am I"? or "What groups do I belong to?" Archaeologies linked to post-processualism answer these questions in multiple ways which vary depending on individual and group engagements in time and space. According to the Jamaican-British researcher Stuart Hall, identity is configured as:

> (...) something formed overtime through unconscious processes and not something innate, existing in conscience at the time of birth. There is always something 'imagined' or fantasised about its unity. It is always incomplete, always 'in the process of', always 'in the making.' (Hall 2005, 38–39)

The unstability of identities is accompanied by the mutability of the various images of culture. If within certain theories it would be possible to work with fixed and predetermined cultural categories which condition identities in the post-processual and postmodern view, "culture" doesn't exist as a solid, homogenous, and single category. On the contrary, it is understood as a fluid process which always varies depending on the interlocutor's view. The latter may or may not share the ethnicities, that is, "practices and

cultural visions of a certain community of people which differentiate them from others" (Giddens 2005, 206).

It must be stressed that all the theoretical currents outlined here are subject to many nuances. Even within processualism there is no consensus about authors' autonomous existence in relation to certain power discourses (Zarankin and Senatore 2002). In this case material culture can take on different roles in mediating the relationships between discourses or between discourses and subjects (Shanks and Tilley 1982; Hodder 1999). In order to understand the role of material culture within these theoretical stances, one must use the teaching tool of highlighting the different intersection points between them as theoretical lines to form a general framework of the ways in which these theories read the world, in terms of both material and intangible culture. This allows us to use them as tools to think about learning processes. André Leroi-Gourhan, for example, fuses biology, genetics, anatomy, material culture, and social life in a beautiful narrative about the innate and the learned. On aesthetics he says:

> These levels, the physiological, technical, social and figurative will here represent the great clusters into which feelings are ordered. In man, references to aesthetic sensibility are rooted in the deepest visceral and muscular sensibility, in dermic sensibility in the senses of smell, taste, hearing and vision; thus, the intellectual image, symbolic reflection of the tissues of sensibility in their entirety. (Leroi-Gourhan 1971, 268)

To outline all aspects surrounding gesture in their organic and artificial paths is archaeology's basic proposal. Reflections on day-to-day social life, practices, and ideas cannot lose sight of the ways in which this knowledge is transmitted and how it expresses human relations.

Gordon Childe's Europeanizing identification of material culture seeks to highlight the tangent points between technical know-how, ethnic expression, and the symbolic feedback of social identity. Tracing the evolution line of European civilization also means a search for the didactic path through which symbols are transmitted as well as recognizing their impact on the day-to-day tangible past and present. What processes are involved in the constitution of the European? How can the right steps toward civilization be taught?

Andrés Zarankin elaborates on the central tenet that materiality, a product of human intention, not only responds to but also configures learning mechanisms in Western society (Zarankin 2001). Far from being built randomly, school space operates within a panoptic logic of control and arranging of ideas, repressing subversive qualities, and defining misbehavior. Walls erected by the state, behind often templelike facades, domesticate the minds of its pupils into sacred and unquestionable dogmas.

According to Andrea Lisset Pérez (2007, 228), education is of paramount importance to understand the socialization processes which reproduce and update different cultural traditions. Although overlooked by anthropology for an important part of its history, the works by Marcel Mauss and Émile Durkheim between the late nineteenth and early twentieth century operated "a fundamental epistemological rupture to understand the educational phenomenon" (Pérez 2007, 228).

In his work *Transmission of social cohesion: tradition, education* (1969), Marcel Mauss sees education as a traditional obligation to socialize new generations (Pérez 2007). Within this mechanism of transmission of cultural habit, corporality, sex, age, and social differentiation are combined into discrete learning phases. Still, new generations are not mere imitators of adults. The fact that their spaces are not clearly defined enables them to cross boundaries that adults no longer challenge. New generations observe the interconnections between practices and knowledge and may refuse to hand them down, bringing about a fresh novelty that may reformulate social processes. Their actions – e.g., games – are not mere reproductions, but creative constructions of the social world's meanings.

It is in this contest that new proposals mobilize contemporary archeologists to perceive themselves not only as interpreters of the materiality produced by past bodies and the past bodies produced by materiality but also their own present socialized body. While the scrutiny of the discourse outlined the biopolitics involved in the construction of truth, the real effects of these

strategies on everyday life were lost – the bodies and identities made by discourses became secondary. And by doing so, we ended up maintaining the old proposition of a single universal knowledge, "the discourse," whose intelligibility was the privilege of a few initiates: academic intellectuals. In the words of Danna Haraway, "Who wouldn't grow up warped? Gender, race, the world itself – all seem the effects of warp speeds in the play of signifiers in a cosmic force field" (Haraway 1988, 566–577).

Questioning the excesses of the discursive paradigm, the author seeks a return to objectivity that is not positivist but which is capable of taking a further step toward the creation of truths that allow us to live:

> Feminist objectivity is about limited location and situated knowledge, not about transcendence and splitting of subject and object. It allows us to become answerable for what we learn how to see. (Haraway 1988, 583)

Responsibility is a key word that has occupied international archaeology since the creation of the WAC in the 1980s. A self-awareness also came from social movements against the excesses of totalitarian, colonialist, and imperialist states (and their scientists) around the world. A feminist objectivity, for example, means accepting the limits of one's methods, questions, and self, allowing the emergence of questions and methods of others and their own different knowledges. We can only answer for our responsibilities. No science is done apart from scientists.

Central Questions

Material culture, as we have seen so far, has never failed to be a fundamental element in the development of social relations and identities. Its role in the learning processes of social habitus declares the undeniable alliance between education and archaeology. The question is exactly what such an alliance's powers could be. Both elements have been used to demolish human creativity and impose a massified and eliticized proposal for collective behavior. How should we practice archaeology and education to ensure that they are not "Just another brick in the wall?"

Future Directions

When addressing material culture, we are dealing with physical, materialized constructions. But that material world is still not detached from the intangible contexts which inform these constructions. These correlations – dynamic, fluid, and extremely delicate – can still be grasped when reflecting on the very concept of culture.

Criticisms of normative identities as put forth by civil movements after 1945 allowed for the elaboration of new theoretical proposals for the concept of culture, expressed both in the postwar historic-cultural archaeological trend and in the processualist and post-processualist scopes. As well as the changes in the field of archaeology, multiple perspectives on culture signaled the need to consider the immaterial as a realm worthy of attention from the political sphere.

In this new context, UNESCO's 2003 "Convention for the Safeguard of Intangible Heritage" was formulated with a view to guiding discussion within this new institutional field of research. This "recognizes a deep-seated interdependence between the intangible cultural heritage and the tangible cultural and natural heritage" (UNESCO 2003). For UNESCO, dealing with intangible heritage would be an important way of dealing with materiality itself and valuing human diversity (UNESCO 2005).

Analyzing perceptions about material culture in archaeology, we find it impossible to define material culture without considering its connections with the intangible world, especially if we lose sight of the political consequences of the theoretical models deployed to study materiality. Archaeology deals with material culture, but the basis of its objects of study, the concept of culture, refers to both the material and the spiritual world, so "there is no opposition between the two that can justify a study of 'things' alone (Funari 2003, 10)." Archaeologists' attention must be brought to this correlation between the material and immaterial, and they must also perceive the political consequences of our research.

Among the crisscrossing paths and meanders of new proposals, we believe that the relations between archaeology and education, considering both their material conditions and immaterial

impacts, delineate three paths that deserve our attention:

The first of these would be learning relations between professionals and civil society starting from the professionals' point of view. Regarding that relationship we find that it has been concerns about the preservation of material heritage that have attracted most attention. The effervescence devoted to legal issues and conservationist social engagement are still considered key aims in the eyes of professionals seeking to engage with the lay public.

What we call Public Archaeology today would have emerged from that moment of valuing historic national heritage (Funari and Carvalho 2009). Despite the great value of that struggle and its frequent successes in impeding the excessive penetration of capitalism into places of memory and shared cultural life, we cannot deprive ourselves of a critical awareness of our own interests and practices. Archaeology was, as we have seen, born in the context of both European imperialism and ethnic nationalism; its logic promoted both the ideology of the dominant class and the activities of colonial power (Trigger 1984; Funari and Carvalho 2009).

The varied modes of public coexistence outside archaeology often go beyond our expectations. Over the past 40 years, they have been bravely fighting colonial realities and the normatizations of capitalist society (Funari and Carvalho 2009). Therefore we can't imagine state-sponsored policies of management of this heritage as representing the social totality (Merriman 2004). As well as this, it is fundamental to reflect on the several ways in which learning occurs within these different groups. In this light we must stop considering gaps between our way of imagining the past and local ways of doing so as a deficit on their part that we should somehow compensate (Merriman 2004; Gomes 2006; Holtorf 2007). All societies have their own ways of knowledge and educational practices independent of the existence of schools (Pérez 2007), and it is just as important for cultural differences to be taught as it is for conflicts of interest to be negotiated. We therefore don't believe heritage education to be a way of becoming "culturally literate" (Horta et al. 1999; Bastos 2006), as we don't believe in the existence of cultural illiterates but in several cultural literacies.

This brings us to our second learning relationship between professionals and civil society from the standpoint of civil society. It is exactly at the point when we see ourselves as the teaching elders and devote ourselves to cultivating the immature that new paths come to shake off our most set in beliefs, the time when the educator becomes educated (Freire 1980).

Whether it be in classrooms, fieldwork, or TV broadcasts, extra-academic media that contribute to circulate our work offer us a point of view that lacks scientific parsimony (Taylor 2007) and which is therefore free of our prejudices and obstinacies. As part of the learning process about society, we must bid farewell to our scientific authority, pry open our Pandora's box (Latour 2000), and place our practice at the center of a discussion with those who are its public, consumers and appreciators.

From the 1970s, archaeologists influenced by Marxist or postmodernist theories began to question themselves about the social role of archaeology and especially the bases of the relationships between academics, their research, and society as a whole. The work Public Archaeology by US archaeologist Charles Robert McGimsey, professor of anthropology at the University of Louisiana, is considered a landmark on the route to establishing this new field of archaeology (Merriman 2004, 3). What later became known as Public Archaeology is therefore an area of archaeology which focuses on public interest in general and which developed in order to respond to that very need of dealing with dissonances and conflicts of interest (Merriman 2004, 2).

During the last Meeting of the Brazilian Archaeology Society, in Goiânia/GO, September 2016, Alfredo González-Ruibal presented some thought on archaeology's social and political responsibility in public conflict scenarios. The "public" we work with is a rough definition for anyone who is not an archaeologist; we should remember that there are many "others" outside our disciplinary milieu. On that account, González-Ruibal makes a crucial question: should we really

support everyone's claims? In 2016, Brazilian democracy was mined by a parliamentary coup that gave way to even more elitist and conservative politics, which also gave way to ultraright and pseudo-fascist movements. Ironically, they claim the right to openly speak against immigrants, native peoples, marooners, LGBTQ+, black, women, and laborers. And here the question above falls: should we support racist, sexist, elitist, fascist public claims?

We face still threats against diversity, democracy, and freedom, which must be faced conscious of our situated knowledge. This is the moment to reassemble the bodies disintegrated by postmodernity and carry on a critical and ethical archaeology. We must ask questions that take us toward the respect for diverse ways of living. And our stance is clear: no fascism!

Finally, the third learning relation can be seen internally within the very field of teaching archaeology in higher education. In Brazil the field's growing social importance can be seen particularly clear when we look at the 13 graduate courses that emerged over the past 10 years. But great powers bring great responsibilities, as we argued. In another paper (Ribeiro et al. 2017), we found that important themes such as gender and feminist studies are barely mentioned on the political and educational programs of said courses. The expansion of work markets and training in higher education places the difficult task that we have just outlined in the hands of the old guard, to cultivate unripe fruits while allowing oneself to be reformulated by their novelties and to hand down a discipline that will be ethical, socially responsible, self-critical, passionate about its practice, and conscious of its force. This is the only way we can provide a truly liberating education (Freire 1980).

Materiality in Archaeological Theory

Carl Knappett
Department of Art, University of Toronto, Toronto, ON, Canada

Introduction

Materiality is so enmeshed in our everyday existence that it has a kind of impenetrability. We are in touch with it so intimately that it vanishes. And yet of course it is always very much present. As I write, I sit on a Greek "kafeneio" chair, a simple wooden frame with crisscross rope that leaves its pattern on my legs, at least when I am wearing shorts. The wooden table is simple plywood on dexian. The table, the chair, the wooden floor, the computer, the ceiling fan, the dust, the coffee cups: together they are touched, seen, heard, smelled, and tasted, and somehow despite all these senses at work they go largely unnoticed. Writing brings them momentarily to the fore, though there are other ways too in which they can be made to appear. Many contemporary artists bring the artifacts of the everyday into presence by creating new kinds of encounter with them – from rendering them oversized, as in some of the work of Claes Oldenburg, or at miniature scale as in Slinkachu's almost invisible street scenes, or through redisplay (e.g., Jeff Koons). Sometimes, dramatic events can make the everyday appear to us in a very different light, as, for example, with the house interiors of New Orleans damaged by the floodwaters from Katrina (Wilford 2008). And these two can even come together when contemporary artists redirect their practice in the aftermath of such events, as with the "Floodwall" of Jana Napoli, or the photographic reportage of artist Robert Polidori (Fig. 1). These can help us briefly experience the elusive sense of materiality that is part of our everyday lives.

Arguably, it is the constant exposure to thousands of commodities in the twenty-first century West that forces a kind of drawing back from the overwhelming world of materiality. Or perhaps it

Materiality in Archaeological Theory, Fig. 1 "6539 Canal Street, New Orleans, September, 2005". (© Robert Polidori and courtesy the artist, and Edwynn Houk Gallery, New York)

is the fine-grained engineering of many products that makes our reliance on them so seamless: the thermostats for the silent control of heat in our houses, the ergonomic design of our cars, or the custom orthotics for our feet. But are either of these points valid – is the contemporary world really qualitatively different from the past? In fact, various authors suggest not: that this "condition" is actually part and parcel of being human. We may now sometimes feel choked by materials, but to be human has always been to be material or "artificial" (Taylor 2010). A fascinating set of stories can be traced back through early and later prehistory that document the "gradients" of change in materiality, between, for example, "instruments" and "containers" (Gamble 2007).

Yet despite the integral role of materiality in being and becoming human, the everyday world of stuff is endlessly overlooked both in our everyday lives, and to a surprising degree, perhaps consequently, in our archaeological practice and theory. Although archaeologists necessarily devote much of their attention to things – whether we call them artifacts, material culture, materials, or technologies – definitions of "materiality" have not been forthcoming. While it may seem at one level a term that we might take for granted, a flurry of recent research on materiality shows that it can actually lead in a number of different directions.

Definition

Let us try to think about what defines this phenomenon we call materiality. How is it different from or preferable to some of the other terms mentioned above, such as "artifacts," "materials," or "material culture?" Each of these terms can come across as static and categorical, whereas materiality has the advantage of being more relational. Artifacts imply that only things made by humans are relevant, a shortcoming that materials avoids; the latter could, after all, apply to metal ores, or pebbles on a beach. However, this is perhaps not sufficiently differentiated from the way in which a materials engineer might talk about materials. Material culture more obviously includes the cultural component that concerns the social scientist and humanist, though it does also risk portraying a polarized world of materials on the one hand and culture on the other, with the former acted upon by the latter. Materiality as a term does not make obvious this human component (sociomateriality could be a solution, but is unwieldy). Yet another term on offer is material world(s); this has the advantage of conveying the plural, ensemble quality of human-thing relations, but again it does not naturally include the human, and like "material culture" it too is static. Thus, none of the terms available quite gives us what we

need. Though not perfect, materiality may be the term that gets closest. It does have the distinctive advantage of conveying process, the ongoing dynamic of human-artifactual relations. And it does help to downplay the duality between mind and matter that is really one of the fundamental aims in materiality research (DeMarrais et al. 2004). Though this acts as a useful general guideline, there is an argument for being more specific, which entails considering the multidimensional nature of materiality. In this light, what we need is a concept that can cover four key areas: the dependent (material relations), codependent (social relations), independent (vital), and interdependent (plural) properties of things and objects (Knappett 2012). Admittedly, it is ambitious to try hanging all of these properties on the term "materiality" alone, but this is what it seems to require. One can understand both the reluctance (Miller 2005) and the insistence (Ingold 2007) to define materiality.

Historical Background

It is curious that only relatively recently has the urge to reconnect mind and matter, or the social and the artifactual, been felt. This move notwithstanding material culture is still often described as a reflection or an expression of social organization or cultural ideals. In archaeology, Tim Taylor has attributed this to the deep influence of Gordon Childe (Taylor 2009: 298). Much of the subsequent social archaeology has fallen into a similar Cartesian separation. Indeed, even some of the archaeological literature seemingly aimed at materiality uses terms such as "materialization," which reinforces the idea that something social exists prior to the artifactual, with the former "materialized" in the latter (DeMarrais 2004). Rather than ask here why we see a conjoining of mind and matter reappearing in materiality studies now, albeit unevenly, we should perhaps reflect on what has historically prevented its expression. What is interesting is that, according to Taylor, the sense of an inseparable connection between a community and its artifacts was widely held in the late nineteenth and early twentieth century, with the term "materiality" itself even used by E.B. Tylor as early as 1871 (Taylor 2009: 299). As Taylor also explains, the "sense of the intricate cultural nexus between artifacts and persons" (Taylor 2009: 299) was also tangled up with an essentialism that bound together cultural and racial identity, expressed in the work of Gustaf Kossina, for example, and subsequently subject to political manipulation and abuse in Nazi propaganda. This set of associations evidently led postwar to a disentangling of the cultural nexus to which Taylor refers, with a separation, or even polarization, of the social and the artifactual (actually already expressed in the prewar years by Childe). As an aside, we might note that a similar path was trodden in early twentieth century art history, with Alois Riegl's influential idea of "Kunstwollen" in its formalism promoting the idea of a "cultural nexus," but by the same token also potentially essentializing and hence open to abuse (Elsner 2006). Riegl's ideas generated much debate, with ripostes from Panofsky and Warburg among others (Elsner 2006), and arguably a similar kind of separation of the social and the material as that seen in archaeology.

Despite the postwar backlash against the idea of a tangled cultural nexus binding together a people and their culture, it is not as if the idea ever completely went away. It remained, for example, in the enduring legacy of the Pitt Rivers Museum in Oxford, which has maintained the same organizing principles as originally established when it was founded in 1884, with artifacts arranged according to function rather than geographical origin or period (see Fig. 2). Notable here is that the same E.B. Tylor as mentioned above was keeper of the University Museum of Natural History at Oxford in 1883, adjacent to which the Pitt Rivers was eventually located in 1887, and gave important collections to the Pitt Rivers (Larson et al. 2007). And recently, the Pitt Rivers has been an important stimulus for new work on materiality, not least as the base for Chris Gosden, and more recently for Dan Hicks, both of whom have made important contributions (Gosden 2004, 2005; Gosden et al. 2007; Hicks and Beaudry 2010). And this research base has contributed significantly to the resurgent interest

Materiality in Archaeological Theory, Fig. 2 An example of Pitt-Rivers's approach to artifact categorization. (Originally published in 1875; Pitt-Rivers 1906, Plate III.)

in materiality as a sociomaterial nexus, or what Hodder has recently dubbed the "entanglement" of things with each other and with their human interlocutors (Hodder 2011).

Key Issues/Current Debates

The museum is also a good "laboratory" for thinking about the ontology of artifacts, one of the key issues in materiality studies. If we think about how we engage with materiality in museums, the nature of display is such that we primarily encounter artifacts visually (with some exceptions). This has an objectifying effect whereby we stand back from the artifact as object and consider it consciously (Gosden 2004). This categorical experience of artifact-objects can occur in our daily lives as well, but we are perhaps more accustomed to encounter artifacts in a multisensory way that includes touch, smell, and sound (see opening paragraph). It is this multimodal experience that immerses us in the material world and makes it appear seamless with ourselves. Gosden (2004) talks about this distinction in terms of "objects," on the one hand, and "things," on the other. This distinction does seem to capture something of the shifting ontological status of materiality. It has not been much used in archaeology (though see Knappett 2010), seeing more currency in literary and cultural studies (e.g., Brown 2003). Indeed, it stems from philosophy and the work of Heidegger, whose object/thing distinction comes along with other

distinctions, such as "readiness to hand" and "presence at hand" (Heidegger 1971; Wheeler 2005). When something, such as a hammer, is ready to hand, it recedes from view and is smoothly incorporated into our action repertoires. However, when the hammer breaks, it enters a different mode and becomes present at hand, in which we observe the artifact as object, its categorical properties laid bare as we seek to understand them and return the hammer to use. The interaction between these different modes, if indeed they mark a valid distinction, is little understood and is a key issue for materiality studies.

Another way of viewing what is essentially the same issue is to take a different tack, from a starting point in psychology rather than philosophy. In particular, in the ecological psychology of J.J. Gibson, artifacts are viewed from the perspective of what they can afford an agent (human or indeed any other species) with a particular action repertoire (Gibson 1979). These "affordances" of an artifact are perceived directly by the agent, rather than filtered indirectly through cultural representations. Though a controversial idea in the psychology of perception, it has some common ground with Heidegger's concept of readiness to hand, which implies a kind of direct, seamless perception of an artifact's properties. Archaeologists have made some use of this Gibsonian idea of affordances, but have come up against the problem of how this kind of experience with materiality articulates with a more indirect encounter with the material world, via associations and cultural representations, of the kind envisaged within semiotic approaches to material culture. Again, the issue of the shifting ontologies of materiality arises and how artifacts seem to oscillate between being both objects and things. One solution proposed to the problem is the development of a "situated semiotics," based both on Gibsonian ecological psychology and the semiotics of C.S. Peirce, aimed at addressing both the directness of artifact affordances and the indirectness of artifact associations (Knappett 2005). The groundedness of Peircean semiotics has recently been recognized as an important tool in archaeology for the study of materiality (e.g., Preucel 2006; Crossland 2009) and will surely be an area of lively debate in the years to come.

The issue of the articulation of the direct and the indirect in the ontology of materiality raises another related issue, that of its scale. The notion of affordances is useful for understanding aspects of materiality at an immediate, proximate scale, but through iconic or symbolic associations materiality can occupy scales far beyond the proximate. This has relevance both spatially and temporally. Indeed, the critical role of materiality in allowing early human groups a "release from proximity" has been the focus of important recent work by Clive Gamble, who adopts a long-term perspective stretching from the Paleolithic through to the Early Neolithic (Gamble 2007). Gamble uses a distinction between instruments and containers to chart changing materialities, seeing not so much "revolutions" in material culture, but rather shifting gradients over time in how human groups exploit different material metaphors. The shift toward a more concerted use of containers in the Eurasian early Neolithic, both in the form of houses and ceramic vessels, is thus not seen as a revolution but as a strategic employment of a material metaphor that was already long present, the idea of the body itself as a container. The increasing expression of container metaphors in materials subsequently allowed new expressions of identity to unfold through the Neolithic. One can take this a step further and suggest that a clear idea of the human body as container may not in fact have preexisted the construction of houses and pots as containers, but may only have emerged as an effective bodily metaphor through these materialities (Knappett et al. 2010). If we trace this logic still further forward in time, into later prehistory, we see an explosion of socio-material differentiation in the Bronze Age, with an incredible range of artifacts, often operating together in assemblages (Knappett 2009). One of many possible examples is an assemblage from the "Temple Repositories" in the palace of Knossos, deposited c. 1650 BCE (Hatzaki 2009). This includes a wide range of materials – such as sea shells (both original and faience replicas) female figurines (also in faience), a stone cross, faience cups, and storage jars – that were probably part of

Materiality in Archaeological Theory, Fig. 3 Materiality as assemblage: some of the contents of the Temple Repositories, Knossos. (Courtesy of the Ashmolean Museum)

some cult equipment for use in or close to the palace's central court (see Fig. 3).

This growing differentiation in materialities over the long-term also has a spatial component. The release from proximity not only involves more and more different kinds of artifacts and technologies, but these tend to come from a broader range of more distant places too. If we return to the example of the Temple Repositories, we see faience technology of Egyptian derivation, and imported ceramic vessels from the Cyclades and probably the Dodecanese too. And this is not even an especially "connected" assemblage. Other assemblages we might have chosen from the Late Bronze Age involve more complex networks, particularly if we move further forward in time, to c.1300 BCE, when the complex networks of material circulation are quite astonishing, with "international" trade around the east Mediterranean exemplified in the remarkable cargo of the Ulu Burun shipwreck (Pulak 1998). These networks of materials and materialities can also be seen in the luxury items circulating as part of diplomatic and cultural exchange in the latter part of the Late Bronze Age, c.1400–1200 BCE (Feldman 2006).

Still, these patterns are not often theorized in terms of "materiality." Theoretical debates concerning the temporality and spatiality of materiality have still not been much worked through with detailed archaeological case studies. But a few notable exceptions apart (e.g., Meskell and Joyce 2003; Mills and Walker 2008), much of the debate remains theoretical at present. We might attribute this to the difficulty of talking about materiality in front of specific objects or assemblages – a point made by Elkins with reference to art history (Elkins 2008). Perhaps the issue, as indeed noted by Elkins, is one of methodology. How to go about studying materiality? Archaeology, however, is not short of methodologies, and there are some distinctive approaches already in existence that could be and indeed are being harnessed for a fuller understanding of materiality. As there are some interesting regional differences, though, in these methods, this we will turn to under the next heading.

International Perspectives

When archaeologists do get beyond theoretical considerations of materiality, the methodologies employed see some interesting variations internationally, principally between North America and Europe. In North America, the "behavioral archaeology" developed by Michael Schiffer and colleagues (e.g., recently, Skibo and Schiffer 2008; Hollenback and Schiffer 2010) has given rise to approaches to ancient materiality that examine people-thing interactions from production all the way through to discard. This has not had a lot of purchase in Europe (including the UK), where the *chaîne opératoire*, much used particularly by French lithic specialists, is more prevalent as a means for understanding production sequences alone (cf. Schlanger 1994; Conneller 2008). Instead, another tradition has picked up the consumption and discard end of artifact life histories, focused around issues of structured deposition and fragmentation (Chapman 2000). To understand processes of deposition in the past archaeologists have turned to the present, studying contemporary processes of abandonment (Gonzales-Ruibal 2008; Olsen 2010). In its experiential outlook this differs from the more rigorous attempts at replication in experimental archaeology's efforts to provide insights into past production choices. While the former may seem more post-processual and the latter processual, we should not make too much of such a distinction. For example, while Rathje's US rubbish project might seem processual in its experimental design, Rathje has recently collaborated with Shanks (Shanks et al. 2004); one might also point out the reference to Schiffer's methods in recent work on materiality by Hodder (Hodder 2011). Thus although there are some important differences in approaches to materiality on either side of the Atlantic, these should not be overstated. We should also note that European perspectives on materiality are not confined to the UK and France, with strands of thought established in Scandinavia (e.g., Olsen 2010, see above; also Fahlander 2008; Normark 2010), and emergent in Germany (e.g., Hahn 2005).

Future Directions

While archaeological approaches to materiality are already interdisciplinary, they could benefit still further from a wider range of dialogue. While archaeologists are aware of contemporary approaches in anthropology, sociology and geography, interesting lines of thought are also emerging in history, art history and other related disciplines. Tapping into approaches from many domains of inquiry is an essential direction for the future of materiality studies, as materiality itself has so many dimensions, with complex relations among materials, and between materials and people, and with properties such as vitality and plurality that are as yet poorly understood. Furthermore, archaeology is well placed, with its distinctive set of methodologies for studying people-thing relations, to contribute to the detailed study of materialities through diverse case studies from many periods and places. However, this methodological move has been slow in coming in materiality studies, perhaps, as Elkins states (see above), because of the difficulty of grasping materiality when faced with specific artifacts. This is arguably one of the most important directions for the future – the development of methodologies for the study of materiality that can match and complement the exciting theoretical moves that are currently underway.

Matobo Rock Art

Ancila Nhamo[1] and Camille Bourdier[2]
[1]History Department, University of Zimbabwe, Harare, Zimbabwe
[2]Institut Universitaire de France, Université Toulouse Jean Jaurès, Toulouse, France

Introduction

Located in south western Zimbabwe (Matabeleland South), Matobo, UNESCO World Heritage Landscape has been known by different names including Matopos and Matopo Hills. However, Matobo is currently the official name for the landscape as stated on the UNESCO World Heritage List. Geologically, the area which constitutes the Matobo massif is a giant granite batholith extending more than 2000 km^2 (Fig. 1). Multiple rivers have cut it into a series of NNW-SSE-oriented parallel valleys separated by mostly granitic hills. These provide an extraordinary variety of ecosystems and extensive biodiversity. The cultural heritage comprises exceptional archaeological and living heritage sites. The hills are one of the main locations of rock art worldwide with more than 3000 sites (Mguni 2015). A long history of archaeological research since the 1920s has yielded evidence of peopling from the Earlier Stone Age to the early historical times (Walker 1994, 1995). Some sites have deep Pleistocene-Holocene chrono-cultural sequences that have become reference points in Zimbabwe Stone Age archaeology (Bambata, Pomongwe, and Nswatugi). According to the current data, foragers occupied the Matobo until about 300 AD when the farmers' settlements were established. In addition to the archaeological heritage, Matobo also has places of spiritual and ritual importance to today's local populations within the southern African Mwari religion. Although there is usually no direct claim to a link with the forager art, some of the sites with rock art are considered as sacred which have therefore been considered to be a part of a living heritage by the UNESCO. Although Matobo art has similarities with rock art from other parts of Zimbabwe and southern Africa, there are peculiarities that make it a significant area of research. This chapter focuses on foragers' rock art since little is known of the farmer art of the region so far.

M

Definition

Due to the geomorphological and geological features of the hills, Matobo rock art is mostly found in shallow spheroidal rock shelters of various sizes, from the bottom valleys (Pomongwe) up to the summits (Bambata). Although there are rumors among the general populace about deep cave rock art, these have not been confirmed anywhere in Zimbabwe. Still imagery can also be located on boulders. Rock art sets vary from a handful of images to large assemblages of thousands. Much of the rock art is attributed to the foragers with only a few sites having farmer iconography. Herder art is yet to be identified in the area.

Forager Rock Art

Exclusively painted, the forager rock art comes in the form of the so-called fine-line paintings tradition. Parietal rock engravings are found in other parts of Zimbabwe (Hwange National Park, Bainbridge), mostly in regions with sandstone, a

Matobo Rock Art, Fig. 1 Location map of Matobo (map Google Earth, modif. C. Bourdier)

softer rock to engrave. These paintings are among the best preserved and detailed in southern Africa, and made Matobo so renowned. These show a large range of colors: shades of red, pink, yellow, orange, brown, white, gray, and a few black (Fig. 2). Most were done in solid form with the whole image filled with color(s) while a few were outlined with their inside either left blank or filled out in stripes or other geometric patterns (Fig. 3). Matobo rock art is well known for a sizeable number of bichrome and polychrome paintings with the use of different colors to differentiate body parts on animal depictions, clothes and ornaments on human bodies (Fig. 4). At times, the colors are blended to produce shaded polychromes in a very realistic rendering of the animal coat, especially on antelopes depictions (Silozwane, Nswatugi and Nanke Caves – Fig. 4). Still monochromes prevail. Several instruments were used to paint, from the finger to brushes, and possible feathers, porcupine spikes, sharp bone tools, and/or vegetal stems for the finest lines (Walker 1996).

Rock paintings in Matobo hills depict a wide range of subjects, mostly figurative. Humans prevail together with animals, mainly large- and medium-size herbivores, with also a few felines, fishes, birds, and insects (Walker 1996). Antelopes (kudu, eland, tsessebe, bushbuck) and giraffes are the most commonly represented (Fig. 2). Wildebeests (Fig. 3), zebra, and elephants are much less numerous. The depiction of the animals often bears realistic features that make images identifiable to species level. Special attention was given to the rendering of the coat and sensorial organs (eye, ears, muzzle) often painted in bichromy or polychromy (Fig. 4). These images are very dynamic with lines of walking or running animals as the most common imagery (Figs. 2 and 3). Other scenes include grazing or resting animals. Juveniles are comparatively

Matobo Rock Art, Fig. 3 Solid figures of running humans and outlined depictions of wildebeests at White Rhino cave. (Photo C. Bourdier)

unusual. Human figures come in various forms and compositions (Figs. 3, 5, and 6). Depicted in complete, they show elongated bodies with small rounded heads; some have distorted features. Males are often identified by the depiction of penises which are often elongated, and sometimes infibulated (Fig. 5). Women are indicated by breasts and rounded bellies together with accentuated hips (Figs. 4 and 6). Gender is also reproduced through attributes: items of clothing and specific equipment such as bows, arrows, and quivers for men (Figs. 3 and 5); grinding stones for women. However, men and women indistinctively carry sticks, bags, and baskets. Images are dynamic with a large range of postures which actually individualize the subjects instead of the body traits. The most common composition is lines of walking or running men with the hunting equipment (Walker 1996). These "hunters" are usually associated with potential preys (antelopes, giraffes, elephants), at times with their weapons drawn in a shooting posture (Etopoteni: Walker 1996, p. 47). On some panels, they are depicted carrying the animals, presumably their kill (Mshelele Valley: Walker 1996, p. 48). Few

Matobo Rock Art, Fig. 5 Line of walking men at Bambata cave. (Photo C. Bourdier)

sites show women and female-related activities such as gathering using digging sticks or grinding (Ukhutula, Silozwane). Women can also be seating on their own clapping, most likely referencing to dancing scenes. In very few occasions are men and women executed together as a group, either in walking or camping scenes (Silozwane, Bambata; Fig. 6). Small characters in group scenes could be seen as the depiction of children (Fig. 6).

Matobo rock art also include few various non-real animal beings in the shape of animal-animal conflations (zoomorphics) (Walker 1996). The most iconic of these are the serpent-like conflations with animal heads (Gulubahwe, Buhwe; Fig. 7), in some cases specifically antelope heads. They are often closely associated with human figures, some shown to be crawling along their backs (Gulubahwe) or are intertwined with the serpentine figures (Buhwe). As elsewhere in Zimbabwe, the zoomorphic are an interesting part of Matobo rock art but are not commonly depicted. Except for animal-headed snakes, most

Matobo Rock Art, Fig. 6 Section of the back wall at Silozwane. (Photo C. Bourdier)

Matobo Rock Art, Fig. 7 The serpent zoomorphic from Gulubahwe. (Photo by A. Nhamo)

zoomorphics are found at a few specific sites. Although such figures have a common thread in terms of animal-animal conflations, their meaning seem to be expressed divergently at the individual site level. Human-animal conflations are also exceptionally found. The most common is the human-antelope hybridization, which associates human bodies with antelope head features, especially ears and sometimes horns (Wawa: Walker 1996, p. 51). These include impala and tsessebe (Walker 1996). On a few occasions, humans are also conflated with birds such as ostrich.

Plant depictions are another striking trait. Matobo assemblages mostly contain trees, very often in the shape of naked trunk and branches with a few if no leaves; many are not identifiable to species.

Another common motif in Matobo is the enigmatic depiction known as the formling (Fig. 2). Still in use today, this term was coined by the renowned ethnographer Leo Frobenius to refer to a particular form of images that he could not accurately describe otherwise. Found all over Zimbabwe, these motifs can be described as

"compartmentalized stacks of oval, oblong, or tubular cores" (Mguni 2015, p. 15) which are sometimes encircled. Depicted in monochrome, bichrome, and polychrome formats, some of the most detailed are found in the Matobo. They have puzzled many researchers since the beginning of the twentieth century: figurative motifs? Geometric signs? A diverse range of possible interpretations have been assumed. The most current given by Mguni (2006, 2015) states they are representations of termite mounds or *termitaria* (termite life circle), which are often found with trees growing on them. Mguni argues for a close connection between these formlings, plant, insects (especially flying termites), the fields of flecks, and other geometric depictions. All these are connected to this notion of the spiritual abode, which is considered as God's dwelling among some contemporary forager groups.

Farmer Rock Art

Despite a long history of rock art research, not much is known about the farmer rock art in Matobo beyond the sites location. It is commonly referred to as the "Late White tradition" (Cooke 1974), regarding the fact that most of the images are painted in white kaolin pigment which is significantly different from the ochres used in foragers' paintings. Some paintings were also made with red kaolin. The thick lines were finger-painted demonstrating another radical technical change. The Late White art in Zimbabwe share attributes such a color and texture with the farmer art known as the "White-spread eagled" tradition in South Central Africa (Eastern Zambia, Central Malawi, Central Western Mozambique – Smith 2005; Zubieta 2016). However, the Late White tradition depicts crude geometric motifs, animals, and humans rather than the iconic spread-eagled designs found in northwards. Nevertheless, contrary to the forager tradition, animals and humans are seen front view or from above, with very schematic geometric lines, no internal details, and lack any dynamism. The motifs are juxtaposed or superimposed with no apparent interaction.

Key Issues and Current Debates

Dating

Dating and chronological sequencing is one of the key outstanding issues pertaining to Matobo rock art, and more broadly to southern Africa (Swart 2004). Indeed the rock art of the whole region lacks chronological markers. According to the current data, southern Africa seems to be the cradle of graphic expression with geometric patterns engraved on pieces of ochre, stone, and eggshell from 100,000 BP (Henshilwood et al. 2009; Texier et al. 2013). Yet surprisingly, the oldest rock art with directdating at present is only between 5723 and 4420 cal. BP (Bonneau et al. 2017). The existence of a regional Pleistocene rock art is still at stake. Moreover, this question tackles another central issue in History of Art and Prehistory: the emergence of rock art in comparison to portable art, the seemingly discrepancy between the two, and the factors of this crucial cultural and social shift within the visual productions.

Although a number of chronometric dates have been established for the Matobo, they are still inadequate to provide a clear and convincing chronology of the rock art. Walker (1995, 1996) has obtained dates from associated material found together with painted spalls, pigments, and painting equipment in the archaeological layers at Pomongwe and Nswatugi. These include the oldest date of around 13,000–12,000 BP at Pomongwe, which makes Matobo one of the very few spots in Southern Africa with probable Pleistocene rock art. It is a minimum date as it indicates that rock paintings were already being done by this time for spalls to have peeled off and be incorporated in the stratigraphy of the rock shelter. Walker also recognized depictions of some ancient animals such as a zebra species (*equusgreyvi*) at Bambata, known to have gone into extinction some 9000 BP, which becomes an *ante quam* date for such images. Moreover, one often assumes that some Pleistocene rock art assemblages could have remained on walls in the deepest rock shelters thanks to the stability and low erosion rate of granite and a low exposure to sunlight and water weathering (Nhamo 2014).

Therefore, the actual date for the beginning of the practice of rock art is still outstanding. Dating of the subsequent development of the rock art is also vague and elusive. Relying on the archaeological sequences from the sites he excavated, Walker (1996) provided a provisional chronology, which puts much of foragers' art between 10,000 and 1500 BP when the foragers' populations would have had to leave the massif pushed away by the farmer community's first settlement.

Stylistic Sequencing

Stylistic sequencing has been at the center of controversy with long-running debates not just in Zimbabwe but also for southern Africa as a whole. The arguments surround the methodologies and even the heuristic usefulness of the stylistic approach in an interpretative perspective (Lewis-Williams 1990; Garlake 1995; Pearce 2010). Matobo rock art shows elements of variability in the techniques (shades, number, and associations of colors), and in the human and animal forms and compositions. The main sites appear as palimpsests with multiple superimposed layers of paint, which suggest changes over time, notably in the techniques, selection of motifs, and scenes. Such stylistic variations could attest to cultural dynamics as known in other fields of the foragers' material culture (lithics, hunting equipment). They could even yield evidence of changes of meaning when considering motifs and compositions (Pearce 2002).

In Zimbabwe, these were the mainstay of rock art studies from the 1940s through to 1960s and 1970s. The major reference for the stylistic sequence has been Cran Cooke (1963, 1974) who defined seven stylistic phases. Drawing on some of Cooke's conclusions, in Matobo Walker argued for a progressive technical improvement in time with first monochromes (Pleistocene), then bichromes (from 9000 BP), and latest polychromes (6000 BP). Mguni (2002, 2015) made similar implicit use of these sequences, as Peter Garlake (1995) and Ancila Nhamo (2014) did elsewhere in Zimbabwe. These traditional stylistic sequences have been heavily criticized for lack of objectivity and consistency in the choice of analytical attributes. Scholars have also pointed to the unsystematic methods used in establishing the sequences and the difficulties in replication when applied to several sites (Garlake 1995; Mguni 2002; Nhamo 2007). In South Africa, modern methodologies such as the Harris Matrix have been applied to the art as a way of refining these sequences. However, these works have also become embroidered in fierce debates over the applicability of the method (Swart 2006; Pearce 2010; Russell 2012). Nevertheless, modern researchers continue to use these "faulty" traditional sequences in Zimbabwe due to lack of updated chronostylistic studies.

Regional Variation of the Rock Art

Four provinces have been defined in Southern Africa foragers' rock art, one of which is the Zimbabwe-Limpopo with Matobo (Garlake 1995; Eastwood and Eastwood 2006). Several recent works have yielded evidence of a complex interplay of continuities and specificities in the techniques and motifs within the province (Walker 1996; Mguni 2015). For instance, Matobo bestiary shows some particularities with the importance given to giraffes, the higher frequency of elands than elsewhere in Zimbabwe, the depiction of the wildebeest, and the scarcity of elephants (Nhamo 2014). Plant depictions differ from other regions in Zimbabwe, notably the Mashonaland where tubers are the most common. In the technical field, the substantial use of color with polychromy is a major distinction as rock paintings are predominantly monochrome elsewhere (Garlake 1995; Walker 1996; Nhamo 2007, 2014). Walker (1996, p. 28) argued that the colors seem to give meaning to some images since there is some consistence in those used on certain images such as kudu, eland, and wildebeest. These differences with other parts of Zimbabwe and southern Africa have already been noted but little explanation has been proffered for the variability (Walker 1996). They may allude to local cultural facies and help recognizing and characterizing cultural dynamics within the past foragers' populations not only in time but also in space. They could also testify to local meanings of rock art production. Regarding the formlings for instance, although Mguni's interpretation is one of

the most convincing, he acknowledges that the basis of his arguments are not replicated on most sites since formlings are sometimes depicted on their own (2015, p. 124). The variation of some symbols use in different parts of Zimbabwe has to be investigated. Thus, understanding the regional variation of motifs remains an outstanding issue.

Interpretation

A last key issue regarding Matobo rock art with which most regional studies have dealt is interpretation, a seemingly never-ending endeavor in the discipline. Because of the existence of a bestiary with specific animals within the fauna, the absence of landscape elements, the non-representation of most daily activities, or the presence of nonreal beings, the vision of a decorative purpose or an "art for art's sake" (Cooke 1963, 1974) has been abandoned in the 1980s. Based on the exceptional informed ethnographic documentation from San populations of the nineteenth and twentieth centuries in South Africa, scholars agree to consider this iconography as the metaphoric expression of foragers' spirituality and religion with the depictions of magical potencies embodied in animals, beings from the spiritual world, mythical characters, together with the depiction of actual ritual activities (dancing scenes). Such as all regions with forager rock art in southern Africa, the predominant interpretation is Lewis-Williams' shamanism (Lewis-Williams and Dwoson 1989), i.e., the rock art would depict visions and experiences of shamans, and shamanistic rituals. Some have argued for a wider spiritual symbolism. Hunting, for example, has been interpreted under shamanism theory as symbolizing dying shamans (Lewis-Williams and Dowson 1989). However, Dowson (2007) later claimed that depiction of hunting represents the relationship between the hunter and the hunted where the hunter is procuring food while the hunted is providing sustenance. This engagement between the human and nonhuman leads to regeneration of life. The hunter respects the hunted for this role. The frequency of the hunting iconography shows that it was significant symbolism in the production and use of rock art in Matobo. It is likely to have permeated many aspects of culture beyond just spirituality. This has also been demonstrated by Mguni's (2006, 2015) re-visitation of the famous formling images. His extensive study of formling and their association with botanical imagery, mainly from Matobo, has brought out new insights into the symbolic meaning. For some, besides spirituality and ritual activities, rock art addresses a wider range of social symbolism including social identity negotiation, i.e., gender, groups, affiliations, and social networks identification (Garlake 1995; Nhamo 2013). Still none of these interpretative theories can explain all the motifs and compositions found in Matobo rock art so far. Many other features of the iconography still require further investigation such as conflated animal-human figures, gathering scenes, and camping scenes for instance.

Future Research Directions

The generalized social context of the art has been established through regional works on southern Africa such as those by Lewis-Williams and Dowson (1989). What is now necessary are specific localized studies to contextualize the environmental, economic, social, and political conditions that surrounded rock art production and reception to provide a better understanding of the meaning, social functions and uses (Dowson 1994). Indeed, with regard to the sociocultural dynamics in space and time attested in the techno-economic equipment, it appears essential to set the foragers' rock art back in a historical perspective (Mitchell 2005). It is both a necessity and a major scientific challenge that has drawn the interest of several researchers in recent years (Hampson 2015; Pearce 2002). Moreover, if one considers images as media of information within social relations (Wiessner 1984), rock art can augment the reconstruction of information exchanges, past social networks, and territorial structuring (broad vs. reduced; open vs. closed; socioeconomic risk minimization vs. competition), and their dynamics through time (McDonald and Veth 2012). It is, therefore, imperative to integrate rock art into broader researches on the past societies, notably in the exploration of identity and settlement

history of foragers' populations, and to tackle the complex relations between rock art production, socioeconomic systems, settlement patterns, and environment. How do environmental conditions and related socioeconomic structuring impact rock art? Conversely, how and to which extend can changes in style inform on foragers' socioeconomic organization? Since Walker (1995) has already made such attempts, Matobo is an ideal starting point for this kind of research in Zimbabwe.

To address the current key issues and to develop these new challenges in the future, there is now an absolute need for exhaustive and updated documentation according to the modern scientific standards. Although many works have been conducted in Matobo, the documentation is limited, partial, and irregular. A major aspect of rock art research should consist in the systematic survey recording tracing of the paintings. In addition, archeometric analysis should be carried out to characterize paintings recipes and pigments sourcing. This enhanced documentation should help refining the stylistic sequence through multi-criteria analyses of the assemblages including technological studies. As argued above, reviewing of stylistic sequences is not only relevant for chronology, but aides in addressing another key issue in Zimbabwe and southern African rock art studies, i.e., regional variation of rock art motifs. The studies on variation in Matobo and elsewhere should be hinged on a clear understanding of the patterning of the motifs across space and time to determine whether the differences are a result of localized factors or temporal changes. Priority should also be given to a search for relevant chronometric dating systems whenever possible to counter the inherent limitations of the relative methods. Indeed, dating rock art directly would contextualize and historicize the art by making it easier to chronological developments over time. However, chronometric dating techniques such as AMS are limited by the lack of organic pigments used in Matobo rock paintings (i.e., few black paintings). Thus, a refinement of the paintings stratigraphies through modern systematic analytical tools is still crucial.

Studies must now include an interdisciplinary approach, especially in relation to ground archaeology (Mitchell 2005; Meskell 2009). Indeed the other archaeological materials unearthed in the same sites are essential to inform on the chronocultural attributions of the rock art, and on the activities related to the production and reception of the paintings to provide knowledge of both the meaning and the social uses of rock art. This interdisciplinary dimension of rock art research must combine new excavation programs to provide updated stratigraphies and chronologies, and the re-examination of the archaeological series (artifacts and ecofacts) from previous excavations. For Matobo, this should be a central aspiration as some of the main rock art sites were excavated in the twentieth century, notably by N. Walker (1995). Walker collected all the painted spalls and painting equipment, but most of them have not been analyzed and remain unpublished.

Matson, Frederick R.

Charles C. Kolb
Independent Scholar and Retired: Division of Preservation and Access, National Endowment for the Humanities, Washington, DC, USA

Basic Bibliographic Information

Frederick Rognald Matson, Jr. (July 29, 1912, to March 27, 2007), a native of Chicago, Illinois, USA, was an influential archaeologist, university administrator, and pioneer in the scientific analysis of archaeological ceramics, glaze, and glass. He received a BS in ceramic engineering from the University of Illinois (1933) and was a graduate student in ceramic engineering at Carnegie Institute of Technology (1933–1934), before receiving a fellowship to attend the University of Michigan (1934–1936). Attaining an AM in anthropology at Michigan (1936), Matson enrolled in a newly developed graduate program in ceramic archaeology combining engineering and archaeology and was a Rackham Predoctoral Fellow (1938–1939), receiving his Ph.D. in ceramic archaeology at Michigan (1939) after defending his dissertation, *A Technological Study of the Unglazed Pottery and Figurines from Seleucia on the Tigris*. He served as field archaeologist on Michigan's expedition to Seleucia on the Tigris [Iraq] (1936–1937) and worked with Carl Guthe and James Griffin to develop the "Ceramic Repository for the Eastern United States" at Michigan (1937–1938), becoming assistant curator of ceramics in Michigan's Museum of Anthropology (1939–1942).

During World War II, Matson served as assistant ceramic engineer in the Optical Glass Section of the US National Bureau of Standards (1942–1944) and was appointed head of the Glass Section of the Armstrong Cork Company Research Laboratory, Lancaster, PA (1944–1948). He joined the Pennsylvania State University where he would spend the next three decades, initially in the College of Mineral Industries as professor of ceramics (1948–1953) and then as professor of archaeology, College of Liberal Arts (1953–1957), assistant to associate dean for research and director of the Social Science Research Institute in the College of Liberal Arts (1957–1966), and professor of archaeology in the newly established Department of Anthropology (1966–1978) (Kolb 2018), retiring as professor emeritus of ceramics and professor emeritus of archaeology in 1978 but continuing to work into his 90s (Kolb 1988a, 2018).

Major Accomplishments

Matson as a ceramic engineer, archeometrician, ceramic ethnoarchaeologist, and ethnographer combined these disciplines in his field and laboratory research and teaching. As an academic, he conducted annual summer fieldwork and research (1948–1975) on ceramics fabricated in contemporary pottery-making communities – what became ceramic ethnoarchaeology – in societies geographically spanning Spain to Afghanistan (1936–1975). In addition, he was the ceramic analyst archaeological expedition studying materials from Neolithic through the Late Islamic periods located from the

Charles C. Kolb has retired.

western Mediterranean through the Near East to Afghanistan. He also undertook ethnographic studies of modern pottery-making communities living on or near two dozen important prehistoric and Classical sites including Dura Europos, Jarmo, Persepolis, Tarsus, Pylos, Lerna, Porto Kheli, Franchthi Cave, and sites in Messina, Sphynos, and Athenian Agora. Matson particularly enjoyed working on the University of Chicago Oriental Institute projects directed by Robert Braidwood, and as early as 1953, he collected charcoal and bone specimens used for some of the earliest radiocarbon dates; in addition, he worked with Ralph Solecki at Shanidar Cave and village.

Initially, ceramic studies were confined to footnotes and often obscure descriptive catalogues in the appendices of site reports, but Matson, Anna Shepard, and a few other scholars demonstrated conclusively that the analyses of archaeological pottery could shed light on the people who made and used ceramic vessels and other clay objects. Hence, he was instrumental in bringing pottery out of appendices and into the mainstream narratives of archaeological reports and into full explanatory volumes devoted not only to form and function but also the holistic process from locating raw materials, fabrication, firing, distribution, and final disposition, reuse or discard.

Matson organized and convened the "Ceramics and Man" Wenner-Gren Conference in Burg Wartenstein, Austria, September 2–12, 1961. The international participants included a then "who's who" in ceramic studies: Robert Ehrich, Sigvald Linné, George Foster, Anna Shepard, Irving Rouse, James Griffin, H.W.M. Hodges, J.D. van der Waals, Walter Trachsler, Hélène Balfet, Zaky Iskander, Saul Weinberg, Frederick Matson, James Mellaart, Ruth Amiran, Louis Vanden Berghe, Wilhelm Solheim II, and Irving Rouse. The Matson-edited monograph, *Ceramics and Man*, containing 20 chapters, was published in 1965 and included his contribution "Ceramic Ecology: An Approach to the Study of the Early Cultures of the Near East" in which he stated that "unless ceramic studies lead to a better understanding of the cultural context in which ceramic materials were made and used, they form a sterile record of limited worth" (1965:205). The concept has been modified and expanded (Kolb 1989, 2001, 2011). Matson published nearly 60 articles and book chapters (Kolb 1988b); a sample of his major contributions appears in "Further Reading."

He was particularly proud of his students – mostly Penn State Mesoamericanists – who learned ceramic analysis, interpretation, and experimental archaeology in his laboratory, notably Prudence Rice (1987), Robert Johnston, Louana Lackey, Charles Kolb, Robert Santley, and James Sheehy. Early in his career, a new Penn State faculty member, Dean E. Arnold, was also influenced by Matson's ecological approach. Matson, as Dean for Research in the College of the Liberal Arts (1957–1966), was grantsman for nearly a dozen academic departments and oversaw the preparation and submission of grant proposals to funding agencies and the administration of awards. Archaeologists Louis Dupree and William Sanders and human biologist Paul Baker's multiple applications and subsequent awards reflected Fred's mentoring.

Matson was a founding member of the Society for American Archaeology (1932), gave the American Ceramic Society's Edward Orton, Jr. Memorial Lecturer "Ceramic Archaeology" (1953), and served as president of the Archaeological Institute of America (1975–1976) and received the AIA's Pomerance Award for Scientific Contributions to Archaeology (1981) as well as the Society for American Archaeology's Award for Excellence in Ceramic Studies (1995).

Fred's wife, Margaret Benson Hart Matson (1908–1995), joined the Penn State Sociology Department in 1953 rising to department chair and retiring in 1978 as professor emerita of sociology and social welfare. She served as president of the Pennsylvania Sociological Society (1958–1959) and then began a 20-year career with the US Commission on Higher Education, in the planning and implementation of study abroad program evaluations. Margaret and Fred were childless – their "children" were their students – but invested substantial energy and funds and donated ethnographic artifacts to create what became Penn State's Matson Museum of

Anthropology (Kolb 1988a). Fred was honored by two edited festschriften, one by Rice (1984) and another by Kolb and Lackey (1988); he is also honored by the yearly Ceramic Ecology Symposium held annually at the American Anthropological Association meetings (1986 to present).

Matveeva, Galina I.

Natalia P. Salugina
Samara State Academy of Culture and Arts, Samara, Russia

Basic Biographical Information

Galina Ivanovna Matveeva (1933–2008) (Fig. 1) was a Professor and Chair of Russian History at the Samara State University, candidate of historical sciences (scientific degree Ph.D.), founder of archaeological scientific school in Samara State University, President of the Samara Archaeological Society, and the author of more than 120 scientific works and manuals.

Matveeva, Galina I., Fig. 1 Galina Ivanovna Matveeva

Galina Matveeva was born on July 27, 1933, in the city Ashe, Chelyabinsk region, Russia, to the family of a history teacher. From 1951 to 1956, she was a student of the Historical-Philological Faculty of the Perm (Molotov) State University. Her scientific leader at that time was O.N. Bader – a great scientist, talented teacher, and agreeable person. In the university, Galina Matveeva learned the skills of fieldwork and gained fundamental theoretical knowledge of archaeology. The years 1956–1961 were the time of work in Troitsk, the city in Chelyabinsk region, as the director of a regional museum of folklore. During these years, Matveeva carried out extensive archaeological investigations, researching burial mounds, which have been destroyed since through construction, and deposited the excavated treasures into museum collections. From 1961 up to 1969, she worked in the Bashkir State University. This was a fruitful period for her, during

which she determined the main sphere of her intellectual interests – early medieval archaeology (though she was also interested in Neolithic and Bronze epochs). In 1970, she defended her doctoral thesis at the Archaeological Institute of the USSR Academy of Science.

Beginning in 1969, Matveeva's life was closely connected with the Samara (Kuibyshev at that time) State University, where she lectured on archaeology, history of primitive society, and ethnography. The Samara (Kuibyshev) region badly needed research from an archaeological point of view, and Matveeva began her archaeological exploration practically from the scratch. She started the investigation following V.V. Golstein's legacy and founded the Middle-Volga Region Archaeological Expedition in 1970, which still exists, focusing on different places in the region and in the country.

Major Accomplishments

G.I. Matveeva investigated many archaeological relics of the past, including the barrow of the Neolithic epoch near the village Sjeszheye (undertaken in cooperation with I.B. Vasiliev); Bronze period miners and metallurgists' settlement by Mikhailo-Ovsyanka; seventh and eighth ages CE tumuli with iron facings, connected with the early Bulgar tribes coming to Middle Volga from southern areas; Murom settlement, the southern outpost of the Volga Bulgaria of the tenth to thirteenth centuries and the only big town in the Samara region; and Suhorechye settling – a handicraft settlement of the Golden Horde. Matveeva's research resulted in the discovery of the "Novinkovskiy" cultural type.

Above all, Matveeva was interested in the medieval times. She constantly carried out research of the Imenkovs' culture and its monuments. She found the origins of these people in the upper Dnieper region, traditional places of settlement of the Slavs and the Balts. She determined their ethnicity as Slavic. In 1982, she investigated Lbische mound and identified the Lbische cultural type, dating third to fourth century CE. She formulated the hypothesis concerning the genetic relationship of the Imenkovs' culture and Slavonic people. This is a leading hypothesis in modern science, which is supported by most researchers who study the Slavonic culture.

G.I. Matveeva's last years were devoted to studying the relations of the Imenkov people with Turkish-speaking Bulgarian tribes and the historical fate of these people.

In Matveeva's scientific work, we clearly see her personality: meticulous, principled, brave, sensitive, intuitive, and knowledgeable. She was a nice teacher, and many well-known Samara archaeologists emerged from under her scientific guidance.

Galina Ivanovna published 120 scientific works. In the history of archaeology, she is one of the leading specialists in medieval history of the Volga region.

Maya Forest Garden

Anabel Ford
MesoAmerican Research Center, University of California Santa Barbara and Exploring Solutions Past: The Maya Forest Alliance, Santa Barbara, CA, USA

Defining the Maya Forest Garden

Today, as in the past, the Maya forest is known for its remarkable diversity and abundance of useful plants (Fig. 1). Far from the popularized notions of a pristine forest untouched by humans, the Maya forest is a co-creation of the human-environment relationship crossing time from the ancient Maya to the present. A product of millennia of resource management practices, the modern Maya forest is a domesticated landscape and serves as a veritable garden (cf. Anderson 2005), among the most biodiverse forests in the world and of a conservation concern (Mittermeier et al. 2000). Skilled Maya farmers, also known as master forest gardeners, whose heritage links to the ancient Maya landscape, use the forest as a garden and build utility in their agricultural landscape through the practice of the milpa-forest garden cycle.

Economic botanists say the Maya forest is a garden, filled with useful plants important to the Maya and to the rest of the world. This remarkable and abundant forest was featured on the historic global scene after the brutal conquest of the sixteenth century from whence its ecological treasures and harvesting techniques were exposed to the world. The garden's natural resources grew in demand affecting economies and cultures in subtle yet profound ways due to its novelty and quality, the Spanish grew a dependence on the native honey in the seventeenth century, the British used logwood as a base for dyes in the eighteenth century, European cabinet makers relied on mahogany in the nineteenth century, Wriggley's made a fortune in chicle gum of the Chicozapote, and ship rigging needed henequen fibers in the twentieth century, to name a few.

Traditional Maya forest gardens are a legacy of the ancient Maya and hailed as the most diverse in the world (Campbell 2007). Defining the forest garden is the essential step to understanding the Maya forest garden. Humans have interacted and shaped their environment over tens of thousands, even millions of years.

Originating in Africa and radiating out through Eurasia and ultimately into the Americas, the dynamic human engagement with the environment has left a mark. Using fire and stone tools, humans early on had great potential to modify their surroundings and influence the composition of the landscape. A forest garden represents an historical ecological setting that reflects the cumulative needs and values of the people who managed that setting, from house lots to habitats and landscapes. The Maya forest garden is an anthropogenic wooded landscape based on swidden, where human choice with cutting and burning is integral to the natural regeneration (Conklin 1954; see also Chazdon 2014). The consequent landscape reflects cycles of selection favoring daily human needs with annual crops opening gaps giving way to useful perennial woodland canopy. This legacy, however, is being practiced in ever fewer numbers as traditional ecological knowledge is eschewed for modern technology, and the encroachment of mechanical farming and urbanization having a distracting effect on the interest and opportunity of the local youth.

Comparative Land Cover and Land Use Change Signatures

How does the contemporary Maya forest reflect the ancient land use systems of the ancient Maya? Humans impacted landscapes worldwide. Today seen as pernicious, the influence of fire and cutting is evident in all the landscapes we see on earth

Maya Forest Garden, Fig. 1 Central Maya lowlands (MesoAmerican Research Center)

today. California is typified with rolling grasslands, but trees have been suppressed by grazing animals introduced by the Spanish that continues into the modern period. The history of the English countryside can be read by the shape and distribution of the trees to reflect invested tending and management. Rice economies of Asia use the bunds, the dykes that separate paddy fields, for

cultivations of crops — trees, and shrubs as well as forage for animals. These are the human land use and management strategies that change biodiversity and impact land cover; this is most dramatic in the tropics.

Biodiversity hotspots have been defined for the tropics around the world, and we can see that there is a relationship between the length of human occupation and the number of, for example, plants that are enumerated (Table 1). The longer the evidence of human presence in the environment, the fewer the overall number of plants. Selection across the millennia favoring the plants and landscapes preferred by humans shows an imprint and perhaps an indication of the tendency of humans to simplify their environment.

The world tropics are the most diverse of habitats and much has been made of the source of that diversity. Nevertheless, there is differentiation in the biodiversity between the Old World and the New World. Africa and South East Asia of the Old World have high numbers of plants, but Mesoamerica as well as the Amazon have been identified with greater diversity, making for the most biodiverse tropical forests. Interestingly, where the great Maya civilization arose and where numerous major cities have been recorded in prehistory, biodiversity is lower than in the Amazon where no major civilizational panoramas developed. Both the Maya forest and South East Asia have supported major preindustrial agrarian societies in prehistory, while Mesoamerica, with 24,000 plants, was occupied for at least 12,000 years and has double the number of plants of South East Asia that was occupied at least 5 times that amount of time. The Amazon, with the greatest number of plants, while settled the same amount of time as the Maya forest, has weathered soil systems restricting areas amenable to agriculture and thus did not experience the same human developmental impacts until the past century.

Maya Forest Garden, Table 1 Tropical biodiversity hotspots after (Mittermeier et al. 2000)

Region	Years of Occupation	Plant Diversity
West Africa	Millions	9,000
South-East Asia	Hundreds of thousands	12,000
Mesoamerica	Tens of thousands	24,000
Amazon	Tens of thousands	48,000

Mesoamerican and the Maya Forest

Mesoamerica, and the Maya forest in particular, have been characterized by plants that are useful to people, and the plants identified in the archaeological record of the Maya are comparable to the forest itself. Today, the 20 dominant plants (Ford 2008) are a prime example of how utility is built into the environment (Table 2) as a product of selection at the family, generation, century, and millennial levels. This utilitarian value of the forest today could only be achieved by centuries of choices by its human inhabitants. Studies show that, from the tallest trees to the smallest shrubs, the forest's qualities reflect uses that are still part of the language of the Maya forest practiced by the region's traditional farmers (Ross 2011). Yet, the majority of these plants are invisible in the paleoenvironmental record, as they are not wind pollinated.

Origins of the Maya Forest Garden

Over the course of 12,000 years of habitation in Mesoamerica, human populations expanded along the coast and overland from the Asian continent, bringing with them stone tool manufacture and fire management skills. Native American expertise lies in their competence and knowledge accumulated over time are fundamental to their adaptations and domestication of the landscapes they encountered. From the Arctic Circle to Tierra del Fuego as hunter-gatherers, dispersed across the continents in less than 2000 years. During the time that these early migrants established themselves in the Americas, they adjusted to the changing climatic conditions that ranged from the cold Ice Age to the warm Holocene Thermal Maximum (Ford and Nigh 2015). It was not until around 8000 years ago that the warm wet tropical forest conditions we are familiar with

Maya Forest Garden, Table 2 Dominant plants of the Maya forest

Scientific name	Common name	Pollinator	Uses
Alseis yucatanensis	Wild mamey	Moths	Food/fruit
Aspidosperma cruentum	Malerio	Insects	Construction
Attalea cohune[a]	Corozo	Insects	Food/construction
Brosimum alicastrum[a]	Ramon	Wind	Food/animal forage
Bursera simarouba[a]	Chaca	Bees	Medicine
Cryosophila stauracantha	Escoba	Beetles	Production
Licania platypus	Succotz	Moths	Food
Lonchocarpus castilloi	Manchich	Insects	Construction
Manilkara zapota[a]	Chicle	Bats	Food/construction
Piscidia piscipula	Jabin	Bees	Poison
Pouteria campechian	Zapotillo	Insects	Food
Pouteria reticulata	Zapote negro	Insects	Latex, animal food
Sabal morrisiana[a]	Escoba	Insects	Production
Simira salvadorensi[a]	Palo colorado	Moths	Construction
Spondias radlkoferi	Jocote	Insects	Food
Swietenia macrophylla	Mahogany	Insects	Construction
Tabebuia rosea	Macuelizo	Bees	Construction
Talisia oliviformi[a]	Kinep	Bees	Food
Vitex gaumeri	Yaxnik	Bats	Construction
Zuelania guidonia	Tamay	Bees	Medicine

[a]Dominant in home gardens

M

dominated the lowlands of Mesoamerica, providing the context for the development of the Maya forest garden.

The rich tropical Maya forest landscape emerged as a cloak over a limestone foundation that continues to have an impact on water distribution, soil formations, plant habitat, and animal dispersal. While current annual rainfall averages 1000 to 2000 mm in the Central Maya Lowlands (Fig. 1), water remains unpredictable on the ground surface across most of the Maya forest due to porous and fractured bedrock. Instead of collecting in watersheds, the water is drawn into underground rivers and caves, opening as lakes in the south and cenotes in the north and moving as rivers in the south-east and south-west.

The woodlands we now know as the Maya forest were shaped by changes transpired in the context of human occupation, and the forest landscape was influenced by the interests of humans (Ford and Nigh 2015). Understanding the relationship between the ancient Maya settlements at the peak of the Classic Period (700–900 BCE) with the tropical woodland environment, demonstrates the association between forest qualities and Maya residential patterns. With preference for the hills and ridges of the uplands, the numbers of ancient domestic architecture were greatest in the well-drained undulating zones, areas preferred by the first farmers and where later civic centers emerged. These are the same zones that today are dominated by useful plants as well as those areas preferred by contemporary forest gardeners (Roys 1931). These rolling hills with friable but shallow and rocky soil are some of the most fertile of the tropical world, inappropriate for plow but ideal for hand cultivation, as the Maya have traditionally farmed and how they manage their own landscapes today. This is a critical point in understanding Maya land use and the integral scope of the Maya forest garden, past and present.

The Maya Milpa Cycle

Maya farmers, like subsistence farmers throughout the world, maintain a home garden (Caballero 1992) along with several secondary plots that leverage different land developments to hedge

Maya Forest Garden, Fig. 2 Infield home garden of milpa and orchard plants (MesoAmerican Research Center)

the uncertainties of weather and crops. Known as the home infield, this base operates (Fig. 2) as the core that is coordinated with multiple secondary outfields, the cycles of open crops, secondary shrub and tree cover, and closed canopy forest gardens are enhanced over the development cycle that is a minimum of 20 years (Fig. 3). With annual variability in rainfall, as well as the seasonal cycle of precipitation, farmers today, and certainly in the past, favor established cropping in home infield plots for their intensive labor investment and dispersed outfield areas to improve the production challenges that vary with too much or too little rain. This system builds food sovereignty for the farmer and security for the family, supporting the redistribution of resources that are required by the local community.

This infield-outfield pattern of land use (Netting 1989) contributes to a complex landscape that sequences from forest to field and back to forest again with each family, generation, century, and millennial cycle (Table 3). Working within the natural regenerative system, swidden in general and the Maya agricultural cycle in particular, is

Maya Forest Garden, Fig. 3 The stages of the milpa cycle (Kippy Nigh)

integral to the Maya forest (see Conklin 1954). This is evident in the wind pollination syndromes that favor the open and succession phases and will be more evident in the paleoenvironmental record. Built on a basic 20-year field to forest cycle, the Maya Milpa forest garden cycle intervenes in the natural succession process (Chazdon 2014) to direct the production of the landscape to human ends. In forestry terms, the opening for crops is equal to the forest gap. But this is an intentional

Maya Forest Garden, Table 3 Dominant plants of the Maya milpa forest garden cycle[a]

Maya Forest Garden, Fig. 4 Complex milpa outfield with tobacco, sugarcane, maize, banana, among other annuals (James Nations)

gap focused on the diverse cropped milpa field (Fig. 4).

Swidden, often referred to as shifting cultivation or slash and burn, has been misunderstood. Focused principally on the annual cultivated crops that use only one fifth of the system, the significance of the perennial component is ignored as abandoned. This is far from the case. Using

forestry terms of the sunlit gap, the succession fast growing perennials, and the shaded closed canopy forest, we can better understand the integral nature of the milpa forest garden system and how it is directed to resolve perennial requirements of foods, medicine, and products as well as construction, and other essential household needs. In practice, the cultivated gap is burned with regeneration in mind (Fig. 5). This "gap" is dominated by annuals but contains re-sprouting plants and protected trees to hasten the early succession devoted to building useful perennials (Fig. 6), representing significant investment in trees and shrubs over the cycles of field to forest (Fig. 7). As the crops give way to the perennial phases, the open gap transforms within 8 years, culminating from a plot that was once annual crops to a tiered landscape of understory palms and shrubs that flourish in the shade and trees of valuable fruit, spice, medicine, and construction that make up the structure of the landscape (Fig. 8). The ultimate look of the forest garden may easily be mistaken as wild to the

Maya Forest Garden, Fig. 5 A recently burned field with protected trees and cut shrubs for re-sprouting (Macduff Everton)

Maya Forest Garden, Fig. 8 The Maya forest garden of the Tzunu'un, El Pilar (MesoAmerican Research Center)

uninitiated but in fact is domesticated making the landscape today the *feral* Maya forest (Campbell et al. 2006).

Unlike the impeding compromise implied by Malthus over 200 years ago where he saw field or forest with no way to feed the growing populations, assuming that to produce more food, you needed to clear more forest, the Maya forest garden cycle shows the opposite. It provides food and land cover in an ever-changing cycle that conserves water, inhibits erosion, enhances utility, builds biodiversity, and feeds

people with investment in the biological capital of the landscape. To increase production, investments are in skill and labor, and as the fields are cycled into forests, there are opportunities to manipulate the grasses, forbs, shrubs, trees, palms, epiphytes, all plant species to the benefit of the people, leaving at any one time at least half the area as managed forest habitat for animals (Ford and Clarke 2016). This was the orchard of ancestors that Pakal, the acclaimed ruler of ancient Palenque, refers to on his sarcophagus (Schele and Mathews 1998). In fact, the Maya could not fight the exuberant growth of the forest; they devised an agricultural system that anticipated, selected, and managed that growth to co-create the Maya forest garden. Only with the introduction of the plow and the cow as European management traditions do we see the milpa forest garden cycle interrupted.

Impact of Spanish Colonialism and Imperial Perspectives

The observations of the Spanish at the time of the conquest and colonization are clear about Maya land use and land cover – forest and fields filled the landscape, edible foods lists were extensive, and home gardens were complex (Terán and Rasmussen 1995). The Spanish term *milpa* is derived from the Aztec *Milipan*, or cultivated place. A Milipan could be a field, an orchard, or anything in between. Unfortunately, the Spanish were interested in the product not the milpa cycle, and ultimately their concern was to alter the foreign agricultural system to look more like their own, without understanding how the abundant and diverse foods were cultivated.

The Viceroy Ordinance of 1552 in the Yucatan provides insight into the Spanish impact on the lives of the Maya and ultimately themselves:

> "... se prohibió la presencia de monte dentro espacios urbanos, que todos los pueblos se poblasen al modo de los españoles, [sin milpas en el pueblo] afín que estuviesen limpios, sin sementeras ni arboledas, y si algunas habían se quemasen" (Yam 2009 quoting from the 1552 ordinance issued by Tomás Lopez Medel)

> "... having forests in urban spaces is prohibited, all the towns will construct houses the way the Spaniards do [close to one another] ... [They should not sow any milpa within the town] so that all urban spaces be clean, without sown land or groves; and if there were any, they should be burnt." (Translation based on Roys 1952).

Disavowing the investments in the perennial components of the system, the position of the European ecological imperialist was to misjudge the forest garden (Crosby 1986). Seeing wild forest instead of directed succession towards the forest garden ignored areas without crops as abandoned or worse, fallow (unseeded plowed field).

The Maya forest garden is an intensive perennial system. These so-called abandoned fields are areas of significant investment to build the economic needs of a family, community, area, and region. These perennial "fields" are the source of products used for food, construction, medicine and as a habitat for animals that all contribute to the well-being of the inhabitants. In fact, for every four-year field, there needs to be at least 16 years of perennial management. Far from abandoned, these dynamic spaces represent intensive investments over time and across space, providing the source of the vital requirements of everyday life.

The Legacy of the Maya Forest Garden

Economic botany has brought attention to the important uses of the rich diversity of plants of the Maya forest based on local knowledge (Roys 1931), and applied research in agroforestry (Altieri 2004) has demonstrated the sophistication of the milpa forest garden cycle (Fig. 3). These connections allow us to interpret how the Maya milpa forest garden cycle supported the dense populations of the past and has the potential to contribute to its prosperity and conservation in the future (Schwartz and Corzo 2015).

The Maya civilization prospered in this tropical forested environment. The varied lines of evidence that has been used to argue the destruction of the forest can be interpreted now to show an alternative. Certainly, the Maya had an impact on the nature of the Maya forest, but the result

transformed into a landscape with abundant uses, constructed by the millennial long-term selection of families for the plants and habitats that sustained them. Understanding the qualities of the Maya milpa forest garden cycle clearly demonstrates how the forest became a garden. And this forest garden that underwrote the ancient Maya civilization holds promise for conserving the Maya forest today.

Maya Geography and Culture: Ancient and Contemporary

Beatriz M. Reyes-Foster
Department of Anthropology, University of Central Florida, Orlando, FL, USA

Introduction

The Maya area is "the broad expanse of territory occupied by the Maya in the centuries before the conquest... defined both by the distribution of ancient ruins of Maya Civilization and by the known distribution of peoples still speaking Mayan languages" (Sharer 1994: 19). Maya geography and culture is thus concerned with both the

archaeological past and the ethnographic present. An understanding of the geographic characteristic of this large and diverse territory as well as of the way in which people interacted and continue to interact with their environment is necessary because it informs many archaeological analyses of the ancient Maya.

Definition

Geography plays an important role in cultural production both past and present. The Maya area features great geographical and topographical diversity. Mountain ranges in the northern and southern highlands feature peaks as high as 4220 m (14,470 ft). The northern, central, and southern lowlands show a range of temperate to tropical climates. The southern lowlands have river basins, while in the northern lowlands water is found in underground streams called cenotes (a Spanish cognate of the Mayan word dzonot). Physical environment is much more than just a "backdrop" against which Maya civilization developed and continues to exist. Geographical concepts such as landscape, space, and place enable archaeologists to analyze the ways in which Maya (both ancient and contemporary) built meaningful relationships with their physical surroundings.

Key Issues/Current Debates/Future Directions/Examples

The Maya area covers about 324,000 km^2 (201,325 m^2), spanning from the lower Lempa River in El Salvador to the Isthmus of Tehuantepec in Mexico, encompassing the Yucatan Peninsula, the southern Mexican states of Chiapas and Tabasco, the countries of Guatemala, Belize, Western Honduras, and El Salvador. Sharer notes that these boundaries are diffuse, stating, "the ancient Maya were very much a part of a larger cultural area that has come to be called Mesoamerica" (1994: 19). This area features a variety of terrains, elevations, and weather patterns.

Archaeologists divide the ancient Maya archaeological geographic region by zones (Fig. 1), broadly categorizing them into the Pacific Coastal Plains (spanning from southern Chiapas, Mexico, Guatemala, to El Salvador); the highlands, those areas between 1000 and 2000 m above the sea level (spanning the Mexican states of Chiapas and Oaxaca, as well as Guatemala, Honduras, and northern El Salvador); and the lowlands, those areas between sea level and 1000 m (spanning the Yucatan Peninsula, the Mexican state of Veracruz, and Belize). These regions are inhabited by the contemporary Maya, whose population (an estimated 7,000,000 who speak approximately 29 Mayan languages) is present in all five countries.

The Pacific Coastal Plain, which stretches from southern Chiapas to El Salvador, is a fertile plain at the foothills of the volcanic highlands. Its rich volcanic soils are cut by several south trending rivers, the largest of which is El Salvador's Lempa River. The coastal area has a tropical climate, with annual temperatures between 25 °C and 35 °C (77–95 °F). The coastal plain has been a trading route for longer than any other area in the Maya area, the earliest of which may have been Olmec traders from the Gulf coastal region to the northwest (Sharer and Traxler 2006: 33). Many ancient Maya centers such as El Baúl, Chocola, Takalik Abaj, and Monte Alto are located in the Pacific Coastal Plain (Fig. 2).

Sharer and Traxler (2006) divide the highlands into southern and northern regions. Three continental plates converge in this region, making the southern highlands (located directly to the north of the Pacific Coastal Plain) a very geologically active region. Nevertheless, its rich soils and "springlike" weather continue to make the region attractive for settlement. Today, this area has the largest population density of the Maya area, and the settlements of Kaminaljuyu, El Portón, and Chalchuapa attest to the region's appeal in the past. In contrast, the northern highlands, characterized by Cenozoic limestone formations, are largely undisturbed by geological activity. The ancient Maya quarried the region's jadeite and serpentine deposits. Today, the Alta Verapaz preserve is a habitat of the quetzal bird, whose highly

Maya Geography and Culture: Ancient and Contemporary, Fig. 1 Geographical zones of the Maya area

valued plumes adorned the headdresses of the ancient Maya ruling elite.

Archaeologists have traditionally divided the lowlands into northern and southern areas. Sharer and Traxler (2006) also define the Peten region as a central area, convincingly arguing that this region represents a gradual transition in climate from south to north. The southern lowlands gradually emerge from the northern highlands, from the Guatemalan departments of Huehuetenango, El Quiché, Alta Verapaz, and Izabal. The region is characterized by heavy rainfall, 2000–3000 mm (80–120 in) in a year, and temperatures similar to those of the Pacific Coastal Plain, ranging from 25 °C to 35 °C (77–95 °F) (Sharer and Traxler 2006: 45). The centers of Dos Pilas, Altar de Sacrificios, Bonampak, and Yaxchilan are located in this region. The central lowlands see diminishing rainfall (about 80 in or 2000 mm) and lower elevations (about 300 m) than the southern lowlands. The Peten region of Guatemala, where many important ancient Maya cities are located, is found in the central lowlands. Among the most important sites in this region are Tikal, Calakmul, Palenque, Piedras Negras, Caracol, and Uaxactun. The Maya city of Tayasal

Maya Geography and Culture: Ancient and Contemporary, Fig. 2 Major ancient Maya cities

(which was not conquered until 1697) is also located in this region at Lake Peten Itza. Finally, the northern lowlands, corresponding to the northern half of the Yucatan Peninsula, is characterized by low bush and scrub forest, the terrain is low and flat, made up of porous limestone. There are no surface streams, but underground rivers and cenotes (sinkholes created when the limestone collapses and exposes the water beneath) make up a subterranean water table. Among the ancient Maya sites found in the Yucatan Peninsula are Uxmal, Chichen Itza, Ek Balam, Coba, Dzibilchaltun, Tulum, and Mayapan.

Knowledge of geography as a science and the concepts it contributes to the archaeology of the ancient Maya is necessary for understanding how archaeologists look at the ways the physical setting of Maya civilization relates to its material culture. Geography is a science concerned with the study of physical terrains and the people who inhabit them. It is characterized by two different approaches to its subject: the first is the positivist approach, which considers the qualitative and quantifiable aspects of physical space and human activity; the second is the humanistic approach, which applies concepts from critical and cultural

theory to analyze the actions of human beings and their effects on their surrounding environments. It is from the latter approach to geography that the concepts of landscape, space, and place emerged.

The concepts of landscape, place, and space are particularly useful in analyzing the role that geography plays in the production of culture. Generally, landscape is frequently used in archaeological writing (Anschuetz et al. 2001), and the concept is important in Maya archaeology (Ashmore and Knapp 1999). Rather than seeing geography and geographical features merely as the backdrop against which Maya civilization developed, archaeologists emphasize landscape as "an active and far more complex entity in relation to human lives" (Ashmore and Knapp 1999: 2). In other words, landscape refers to the ways in which human beings build (literally and metaphorically) meaningful relationships with their physical surroundings. As Anschuetz et al. state, "a landscape approach offers strategies and tools that... [construct] the past populated with ideational actors.. rather than 'faceless blobs'... that simply responded to whatever natural environmental vagaries befell them" (162).

Similarly, the concepts of space and place enable anthropologists and archaeologists to think about the social dimensions of location. According to Harry Sanabria (2007), space in this conception "is a construct with spatial (i.e., geographic) coordinates or boundaries with which a landscape is set apart from others based on assumed commonalities or differences" (20). In this sense, the "Maya region," the physical stretch of land encompassing five nations containing the physical remains of ancient Maya civilization, is such a spatial construct. In contrast, the concept of place bundles location, material form, and meaningfulness (Gieryn 2000). Geographically speaking, "place is a particular or lived space" (Agnew 2011: 318). In other words, all places are spaces, but not all spaces are places. The difference between a place and a space is that a place is inhabited and made meaningful by human beings. Within this framework, landscape is the concept used to create an archaeology of place.

These considerations of the role of geography in cultural production are relevant to the study of both ancient and contemporary Mayas. A recent example is the study of ethnoecology in contemporary Yucatan (northern lowlands). The field of ethnoecology considers the ways in which "nature is perceived by humans through a screen of beliefs and knowledge, and how humans, through their symbolic meanings and representations, use and/or manage landscapes and natural resources" (Barrera-Bassols and Toledo 2005: 11). Landscape, then, is constructed through a screen of beliefs and knowledge that informs the way in which Maya people use and manage their natural resources. Archaeologists have used these concepts productively in analyzing how the ancient Maya formed a meaningful relationship with their environment, transforming the space around them into a meaningful place. Using studies of how contemporary Maya people use, manage, and construct their landscapes, archaeologists have been able to construct models of sacred landscapes that have been useful in predicting the location of archaeological sites and in analyzing archaeological remains (Brady 1997; Ashmore and Knapp 1999; Dunning et al. 1999; Smith 2003; Brown 2004).

Researchers have found that Maya people possess more than a mechanistic understanding of their own landscape but construct their landscape through an elaborate linguistic and ritual system that informs the most important act of landscape-making, agricultural practice. Two studies of landscape among contemporary and ancient Mayas exemplify how these concepts are used in archaeological and anthropological research. The first is a study of contemporary Yucatec Maya ethnoecology by Narciso Barrera-Bassols and Victor Manuel Toledo (2005) that analyzes the "sacred ecology" (Faust 1998) of Yucatec Maya landscape management. The second is an influential study by archaeologist James Brady that used a contemporary model of sacred landscape that placed particular importance on caves to predict a pattern in locating architecture in relation to caves at

the Late Classic Maya site of Dos Pilas in the southern lowlands of Guatemala.

The Maya

Anabel Ford
Exploring Solutions Past – The Maya Forest Alliance; ISBER/MesoAmerican Research Center, University of California, Santa Barbara, CA, USA
Department of Anthropology, Grand Valley State University, Allendale, MI, USA

The conventional story of the magnificent Maya civilization ends after 2,000 years with environmental destruction and consequent disappearance of the people. This myth persists despite historical accounts to the contrary. Cortés, on his march to Lake Petén Itzá, describes the area as sufficiently populated to feed and house his retinue of more than 3,000 *Mexica*, gathered from Montezuma's troops, and Spanish conquistadors under arms. Moreover, thirty centuries of population development in the Maya lowlands – stretching from Preclassic to Terminal Classic and through Colonial and present times – represent long-lasting continuity.

The source of Maya wealth lay in their landscape and their profound understanding of how to use it. In fact, the Maya's subtle patterns of land use are embedded within the forest today. To understand the complex historical ecology of the Maya forest requires an examination of contemporary agroecology, traditional farming methods, and the paleoenvironmental record of the Late Classic Maya. Comparing Maya social developments with environmental chronologies reveals a discrepancy between the growth and sophistication of Classic Maya culture and the environmental destruction proposed for its demise. While most studies assume that the collapse of Maya civilization is related to human-caused deforestation, today the Maya forest is known for its remarkable diversity and abundance of useful plants. This suggests contemporary forests in the Maya lowlands are the products of successful land management over long, continuous periods of time. We would not expect such striking ecological conditions if the ancient Maya had radically altered their forested landscape to the point of environmental collapse, and we propose an alternative to this commonly accepted scenario that finds support from archaeological, ecological, and paleoecological data.

A Brief Introduction to the Maya World

The lowland Maya region (Fig. 1) was transformed by humans from the initial peopling of the New World. Human settlers influenced the landscape and ecology from the outset, managing and domesticating plants in a setting that changed from an arid, temperate zone to a humid, tropical environment from 10,000 to 8,000 years ago (Table 1). This environmental change initiated a period of several millennial, called the Archaic, in which human populations intensively interacted with plant communities through mobile horticultural subsistence strategies. Permanent Maya settlements emerged before 3,000 years ago, when communities began to increasingly rely on agriculture while essentially living within the forest. The first Maya villages mark the onset of the Middle Preclassic and were concentrated in areas with secure water reserves, as noted by Dennis Puleston and Olga Puleston (1971). As populations grew, farming settlements expanded to occupy virtually every locale with potential for hand cultivation. The Maya began building impressive monumental centers with public architecture across the lowlands at this time (summarized in Horn 2015: 34–54). Survey data from environs around Tikal, Lake Yaxhá, and the El Pilar area east of Tikal document the near-complete occupation of the well-drained uplands by 2,800 years ago – the same zones that were most densely occupied centuries later during the Late Classic. The growth of Maya farming communities around monumental centers continued to fill in the landscape through the following Late Preclassic period in most areas of the southern lowlands.

Settlement expansion continued between 2,000 and 1,000 years ago during the Classic period that witnessed the apogee of Maya civilization. Much has been made of the so-called Terminal Classic

The Maya, Fig. 1 The central lowland Maya

collapse, a turbulent time when the institution of divine kingship, and Maya political systems more generally, underwent a major transformation. Political capitals in the southern area, which held varying degrees of hegemony over one another and engaged in a near-constant struggle for supremacy at the height of the Late Classic, gradually ceased to be maintained. Public

M

The Maya, Table 1 Occupation chronology: 8,000 years in the Maya forest

Years before present	8,000–4,000	4,000–3,000	3,000–2,000	2,000–1,400	1,400–1,100	1,100–800	800–500	500–present

infrastructure, such as the temples, palaces, and monuments that formed the focal points of Maya cities, was neglected and left to the elements. The idea of collapse, however, exaggerates the reality of this process and suggests a population crash where no such evidence exists (see Webster 2002). Dramatic "collapses" – better envisioned as the gradual abandonment of impressive urban centers – were a signature of Maya culture from Preclassic times and signal transformations of settlement patterns (Iannone 2014), as opposed to drastic reductions in population. Maya populations persisted on the landscape after the so-called Terminal Classic collapse, and significant numbers were still living around centers when the first Spanish conquistadors arrived several centuries later (Alexander 2006).

Hernán Cortés's fifth letter to Charles V, emperor and king of Spain, provides a unique glimpse of the pre-Hispanic Maya (Cortés 1985). Cortés (1985: 355–449) describes his epic *entrada* to the very heart of the southern lowlands at Lake Petén Itzá, some 70 kilometers from the abandoned Classic city of Tikal, in this letter of September 3, 1526. The lowlands that the Spaniards crossed, this "heavily settled region" (Jones 1998: 31; Diaz 1963), were already feeling the effects of the European invasion and dramatic demise of Aztec civilization. Cortés's party traversed Tabasco, Acalan, and Central Petén, where they encountered many large towns, often spaced less than a day's journey apart, separated by "dense forests," groves, and fields (Cortés 1985: 363–386). Even with local maps, as Cortés admits in his letter (e.g., Cortés 1985: 377), the Spanish spent many days lost among forests and bogged down in swamps. Terrified local guides often misled this foreign army as they traversed a region of waterways and well-trod footpaths. Cortés and his large retinue were, nevertheless, nearly always well-billeted and provisioned –willingly or not – by the Maya themselves (Jones 1998: 32–33).

Though the Maya inhabitants fled before him, Cortés was able to find enough food left behind in the well-ordered towns to provision his 3,000 Mexica warriors and almost 100 Spanish horsemen. On his more than 150-day journey from Coatzacoalcos to Tayasal/Nohpeten, the Itzá capital, through hostile territory using only walking trails, Cortés mentions having to sleep in the open air for approximately 17 nights (Cortés 1985: 360–386). The rest of the time Cortés and his army were comfortably housed and fed by the Maya in their own towns. Only between Tabasco and Acalan, in the Kejach territory near Calakmul that now comprises south-central Campeche, did Cortés have to spend several nights in what he called a "depopulated" area before finding a Maya settlement large enough to house his horde.

A careful reading of Cortés's description, Jones's overview (1998), general reflections, suggests that the Maya dwelt prosperously on the forested landscape of the southern Yucatan Peninsula during the early sixteenth century. The productivity of the forest was underscored more than a century later, when the Spaniard Ursua, with his 1697 conquest of the last independent Maya capital Nojpeten, sends a plea of support to Guatemala in which he detailed a list of foods that he and his men were "forced" to eat while traveling from Yucatan to central Petén. Ursua's list included zapote, macal, nance, and other foods found in traditional Maya forest gardens (Schwartz 1990: 54–55). It was a veritable cornucopia of forest resources, but the Spanish had culturally defined culinary standards and found these foods inedible (Terán and Rasmussen 2008: 134).

The agricultural innovation that allowed the Maya to succeed in their tropical ecosystem is known in Spanish as the *milpa*. Essentially in a 20-year cyclic system that opens fields to build forest gardens, this subsistence system sustained the ancient Maya and their landscape, building productivity into every stage of land use. After approximately 4 years, the open field naturally regenerates, managing fast-growing perennials that transform after some 8 years into useful closed canopy forests. The landscape matrix of the milpa-forest garden cycle provides food, builds soil fertility, manages water, maintains biodiversity, sustains animal habitat, and yields forest products and goods for daily life.

Understanding the Mesoamerican and Maya milpa-forest garden cycle as a basic component of the Maya is essential. As a complex polyculture system, it involves the rotation of annual crops with managed stages of perennial forest. The idea

of "abandonment" of fields to lie fallow after several years of annual crop cultivation is a misconception. As Wilken (1987) points out, the "high-performance milpa" is never abandoned even as they are reforested (cf. Terán and Rasmussen 2008). The milpa-forest garden cycle is crucial to the resource-management system that shaped the Maya forest to meet subsistence and tribute needs, develop their political economy, and promote local and long-distance trade.

The Maya Lowland Environment: A Platform for Development

The physical geography of the Maya region creates an environmental gradient, affecting both average annual temperature and rainfall, which is closely tied to elevation above sea level. This gradient extends from the cloud forests in the mountains of Chiapas and Guatemala to the south, around 15 degrees north latitude, through mountain ranges and ridges that gradually descend into the lowland limestone plain of the Yucatan Peninsula, around 21 degrees north. Average annual rainfall varies across the region from less than 500 mm in the northwest Yucatan Peninsula to 4,000 mm in the far south (Fig. 2).

Climate observers in the Maya region traditionally recognize two seasons, the wet and the dry, although local farmers provide a more nuanced view of the seasonal sequence. The rainy season begins in May or June as a warm, wet period associated with tropical air masses and powerful cyclonic storm systems, including hurricanes. A shift occurs in October or November toward cooler wet conditions, which are influenced by subtropical weather systems from North America and include the cold northeasterly winds called *nortes*. Cool, wet conditions persist until February or March, when the rains cease, and a 2- to 3-month dry season begins.

Forests cover a primarily limestone base across the Maya region, and forest composition varies with differences in local climate, water, and soil conditions. The permeable limestone bedrock creates unpredictable access to water, which rarely flows on the surface as rivers or permanent streams (Ford 1996; Iannone 2014; Lucero et al. 2014). Water is instead absorbed into the bedrock through fissures or flows through caves systems as underground streams. Two major river systems, the Belize/New River on the east and the Usumacinta/Candelaria on the west, and several smaller drainages flank the uplifted limestone shelf of the central lowlands. Lakes, lagoons, or cenotes – the water-filled sinkholes prevalent in northern Yucatan – form where the limestone bedrock dissolves to levels below the water table. Water also collects within closed depressions throughout the lowland region during the rainy season.

At least 40 percent of the lowland Maya region comprises wetlands. This is consistent with data from El Pilar, east of Tikal, where poor drainage and wetlands characterizes 38 percent of the area (Ford et al. 2009). Variations in karstic topography and water access generate the following four physiographic regions in the central Maya lowlands (Fig. 3), each containing a different basic ecosystem and capable of producing resources used by ancient and modern people:

- Well-drained ridges and uplands (high-to-low closed forest)
- Poorly drained lowlands (low, open forests and transitional wetlands)
- Perennial riverine wetlands (riparian, aquatic, and semiaquatic vegetation)
- Seasonal closed wetlands (low, open forest tolerant of hydric extremes)

The peopling of the New World altered the character of the environment by introducing anthropogenic landscape modifications at a time of global climate change. In only a few millennia, humans occupied the Americas from the Arctic Circle to Tierra del Fuego. Highly mobile forager groups, equipped with the ability to produce fire and stone tools, fanned out through myriad settings. By no later than 13,000 years ago, humans had spread into all habitable areas of Mesoamerica, including the Maya lowlands. These early occupants were the first to explore the topography of the area and identify sites of permanent water;

The Maya, Fig. 2 Rainfall across the Maya forest

this landscape knowledge was critical to survival at a time when the climate was cool and arid and temperate vegetation prevail. This understanding of the region and its resources provided a solid foundation for responses to future environmental changes.

As the climate warmed and precipitation increased, the dominant vegetation communities in the Maya lowlands began to change. This shift in the regional climatic regime corresponded to worldwide changes known as the Holocene Thermal Maximum around 8,000 years ago, and the

The Maya, Fig. 3 Physiographic regions of the central Maya lowlands

register of plants in the Maya tropical forest is clear. The temperate pine-oak-grass complex diminished in importance, and megathermal taxa, exemplified by *Brosimum*-type Moraceae trees, become evident in the pollen recovered from lake cores (Leyden 2002). The natural range of megathermal plants expanded from northern areas of South America along the eastern (Caribbean) side of Central America up to the Yucatan Peninsula. It is easy to imagine the spread of these plant species and the animals that would have accompanied them – frugivores that depended on the perennial availability of fruits in the warming tropical environment. Humans certainly moved along with these plants and animals, bringing with them additional resources needed for survival. The example of the genus *Theobroma* brings out this point. The genus is

represented by many species in the Amazon yet represented in the Maya forest by only one: *Theobroma cacao*, the natural source of chocolate.

A stable, warm, and wet environment prevailed in the Maya lowlands for approximately 4,000 years (Fig. 4). By this time, with basic knowledge of regional geography – the ridges, the undulating slopes, the wetlands, the lakes, and the few rivers – Archaic mobile horticulturalists were expanding their use of domesticated crops in the context of the forest. Throughout this long period of favorable stable climate conditions, seasonal hunting and gathering activities were governed by seasonal forest production. It was a time of incubation for the Mesoamerican culture that has endured to this day.

Familiarity with the lowland environment was key to building the historical ecological experience of Mesoamerica and the Maya cultures. Climate challenges evoked the development of traditional and local knowledge that continues to inform Mesoamerican agroecology. The paleoecological record of the region, derived from the Petén Lakes (Mueller et al. 2010) and the Cariaco basin sea cores (Haug et al. 2001), shows that precipitation became unstable and unpredictable around 4,000 years ago (see Fig. 4), marking a period of climatic chaos. This turbulent period created environmental stress that dramatically changed the landscape. Alternating wet and dry cycles introduced seasonal rhythms that influenced both flora and fauna. These cycles persist to this day, and they created the conditions that resulted in a new way of life for the Mesoamerican mobile horticulturalists that inhabited the Maya lowlands.

Ancient Maya farmers preferred the well-drained ridges and lower-upland slopes above annual flood lines for settlement (Fedick and Ford 1990; Ford et al. 2009). Today, these are the areas where moist, closed canopy forests develop to their fullest (Schulze and Whitacre 1999). Such forested, well-drained land is

The Maya, Fig. 4 Circum-Caribbean precipitation highlighting the st*able* warm Holocene Thermal Maximum

unevenly distributed across the region, and the dispersed human settlement, characteristic of ancient Maya civilization, reflects the attraction of these preferred environmental zones (Bullard 1960; Culbert and Rice 1990). Ancient centers – and later Spanish relocation – were forced to work against these centrifugal settlement patterns that pulled farmers away from nucleated population hubs and into their milpas (Farriss 1992; Ford et al. 2009). Well-drained hills and slopes comprise less than one-sixth of the area of Northern Belize but nearly half of the Petén interior around the large Classic center Tikal (Fedick and Ford 1990), and these preferred lands are distributed, in varying proportions, to the west into Chiapas and north across the Yucatan Peninsula (Fig. 2). There is a direct relationship between the presence of well-drained ridges, high settlement density, and the location of elite cultural remains of Classic Maya kingdoms.

Historical Debate in the Maya Lowlands

Viewing Maya urbanism through a European historical lens can lead to major misunderstandings and mistaken perceptions. Indigenous peoples in the Americas possessed distinct skill sets that leveraged keen observations of their landscapes and measured environmental potentials against individual abilities. Basic knowledge and observation of the landscape, a fundamental appreciation of the limits of the natural world, and an ability to work *by hand* within those dimensions were fundamental to the growth and development of Maya communities and the forest they inhabited. The forested environment of the Maya lowlands provided a wealth of resources to people who understood how to use and manage their landscape.

The period of climatic chaos, beginning around 4,000 years ago, set the stage for major changes in subsistence, settlement, and social development that characterize the Preclassic in the Maya lowlands. Fundamental to these changes was the shift from scattered and mobile patterns of land use to permanent occupation of hand-cultivable, well-drained areas. As larger populations began to grow and settle in these preferred zones – the same areas where later centers inevitably emerged (Ford 1986: 115–116) – their use of milpa-forest gardens became more intensive. The locations of farming settlements were predicated upon the availability of land resources, and the major Maya centers arose among concentrations of farmers. Control of limited water sources may also have become increasingly political, particularly in the Preclassic, which would have drawn traditionally dispersed farming families into centers as populations grew and the climate became drier (Ford 1996; Lucero et al. 2014; see Haug et al. 2001). This would play a role particularly in the annual dry season.

The currently accepted view of the Maya collapse identifies the Preclassic as the beginning of a period of *escalating* environmental disturbance, which is thought to be linked to increasing population densities across the lowland Maya region (Turner and Sabloff 2012). According to this interpretation, large areas of the central lowlands *were essentially deforested*, with most available land given over to agricultural fields. The perceived result was ecological vulnerability caused by the degradation of the natural resources of the forest environment. This vision of the ancient Maya landscape, however, conflicts with evidence of long-lasting cultural continuity across the region – a continuous 30-century period of population growth and development from the Preclassic to present times.

There is no doubt that land use intensified with Maya growth and development. The steady increase in the number of residential sites through time reflects population growth, as does the proliferation of exuberant monumental civic centers. Scholars have traditionally imagined this landscape overrun by people and fields, where the expansion of settlements could *only* occur by displacing the forest. An alternative landscape for the Classic Maya does not propose settlement and forest as binary opposites, but views forest settlements as integral components of sustainable

human-environment relationships (Atran 1993; Voorhies 1982; see Conklin 1957). With population concentrated in rainforest cities, a form of decentralized urbanism emerged in the largely forested landscape of the Maya lowlands that resembled social developments in the prehistoric Amazon and Cambodia. This model of Maya settlement pattern and landscape ecology, while still debated, recognizes the importance of local solutions to the environmental constraints of the lowlands. The historical relationships between settlement patterns and environment resulted in the creation of the "high-performance milpa" system of food production (Wilken 1987), which is well known among local and traditional farmers and will be discussed in detail below.

Ancient Maya settlements and, by proxy, the farmers that made up the bulk of their population were located near useful forest and field resources. Emerging urban centers depended on these farmers to meet subsistence needs, and farming requirements were integrated into land-use strategies at the local and regional scales. Archaeologists for some time have recognized that the population was dispersed across the well-drained uplands (Bullard 1960), regardless of where the major monumental centers were located (Ford 1986). Social phenomena, such as trade, markets, and political relationships, may help explain these patterns, but their ultimate roots have received little attention from scholars. Recent investigations harnessing the power of geographic information systems (GIS) have statistically demonstrated the strong connections between settlement location and environment (Ford et al. 2009). We will explore these connections in detail to reveal the subtlety of Maya settlement patterns and how they are embedded within the forest environment.

Prehistoric Chronology that Is Native to the Place

Maya chronology represents a long, steady, and successful cultural development in the context of lowland tropical forests. The occupation of the Maya lowlands began with the expansion of hunters and gatherers into the Americas more than 13,000 years ago (González et al. 2008; Lohse 2010; Stinnesbeck et al. 2017). These first people inhabited an arid, cool landscape covering the karstic limestone platform that forms the Maya region. The topography of this area was essentially the same that we recognize today, with undulating ridges and hills interspersed among flatlands.

What began as a cooler, drier climatic regime changed about 8,000 years ago (Haug et al. 2001), when the region became a warm and wet environment with familiar tropical characteristics: evergreen and semi-deciduous, broadleaf-forested uplands, and seasonally or permanently inundated wetlands, with lakes in the south and cenotes in the north. The region was – and remains – subject to periodic Atlantic hurricanes and volcanic eruptions, and it also experiences annual and multiyear cycles of wet and dry periods.

8,000–4,000 Years Ago: Archaeological data from the Archaic period in the Maya lowlands is scant. There is, however, little doubt that people migrated north along the Caribbean littoral during the Holocene Thermal Maximum, at a time when mesic forests were spreading throughout the area. Several lines of evidence support this hypothesis, but none is more prominent than the distribution of plant species in the genus *Theobroma*. While over 100 of species of *Theobroma* have been documented by Kew Gardens, all members of this genus save one, the famous *Theobroma cacao*, are known exclusively from the Amazon. The presence of additional domesticated plants – particularly maize and manioc pollen from northern Belize, dating as early as 5,400 years ago (Pohl et al. 1996) – demonstrates that Archaic inhabitants were manipulating flora and moving closer to relying on food production. Maize, beans, squash, and chile supplemented hunting and gathering, and more intensive cultivation of maize becomes apparent in the pollen record around 4,000 years ago.

Little is known of the scattered and ephemeral Archaic settlements and the annual cycles of the people who lived in them. Diagnostic stone tools from stratified contexts in northeastern Belize (Rosenswig 2004), however, suggest a wide range of hunting and gathering activities were supplemented by incipient horticulture in the emergent tropical forests of the lowlands. Local populations became increasingly familiar with their environments at this time, and there is evidence of settlement continuity between Late Archaic mobile foragers and Middle Preclassic agricultural communities from a handful of sites in northeastern Belize (Lohse 2010). These settlement data suggest that food production was *not* a subsistence innovation introduced by agricultural colonists from outside the region, but an indigenous development that grew from a deep knowledge of the forest environment accumulated over thousands of years.

4,000–3,000 Years Ago: Widespread small but permanent settlements point to major changes throughout Mesoamerica. Very few settlements dating to this time have been discovered in the Maya lowlands, and inhabitants of region continued to practice Archaic lifeways successfully adapted to the forest environment. Outside the Maya lowlands, however, several Mesoamerican communities moved from reliance on mobile horticulture and founded sedentary agricultural villages. Populations increased following the shift to more permanent food production, and the monumental centers of complex societies appeared in highland central Mexico, Oaxaca, and along the Mexican Gulf Coast and Pacific coastal Guatemala within a few hundred years of the first permanent settlements (Horn 2015: 18–24).

Toward the end of this time, and certainly by 3,000 BP, permanent agricultural settlements dotted the forest of the Maya area (Fedick 1989; Ford 1986; Puleston and Puleston 1971). Small centers with public, ceremonial architecture – comparatively modest structures at first, but growing in scale and complexity through time – appeared in Belize, Guatemala, and across the Yucatan Peninsula of Mexico.

The establishment of settled villages and small centers was paralleled by two significant developments in early Maya communities: the production and consumption of pottery and the establishment of long-distance exchange networks that facilitated circulation of valuable commodities (Horn 2015: 26–28). Stylistic similarities among the earliest pottery complexes from the Maya lowlands, including symbolic images and design elements, suggest the widespread flow of information and possibly shared religious ideologies among the earliest settled communities. Valuable nonlocal materials, such as obsidian and basalt from the southern highlands of Guatemala, also appear at lowland centers roughly concurrent with their founding. The relationship between early long-distance exchange networks and the first farming villages in the Maya lowlands is poorly understood, and the establishment of these networks represents an additional break from Archaic lifeways focused exclusively on lowland resources for tool manufacture (Lohse 2010). This initial period of permanent settlement across the forested lowlands marks the beginning of Maya civilization.

3,000–2,000 Years Ago: This pivotal time frame, encompassing the Middle Preclassic and most of the Late Preclassic periods of ancient Maya chronology, witnessed the intensification of several trends across the Maya lowlands. Farming populations continued to increase and expand to encompass the most desirable farmland, such that virtually all upland hills and ridges in the area show evidence of settlement. Modest farming communities grew into large Preclassic monumental centers, and later cities, across the area. The development of impressive lowland centers, and the later rise of urbanism, paralleled the emergence of complex societies in surrounding regions of Mesoamerica (Horn 2015: 30–33)

Settlement pattern and artifact distribution studies indicate the formation of local settlement clusters, comprising multiple independent polities and characterized by intensive intra-cluster

interactions, across the Maya lowlands during the Middle Preclassic (Horn 2015: 36). Intensive interactions at the local scale produced similar patterns of architectural development, burial practices, craft production, and pottery styles within local clusters, while evidence of long-distance exchange clearly demonstrates connectivity among clusters. The formation of complex socioeconomic networks during the Middle Preclassic, and the ability of some individuals and communities to leverage advantageous positions within those networks, was an important engine driving the formation of complex societies in the Maya lowlands (Horn 2015: 662–679).

The development of complex societies across the Maya lowlands allowed some sites, such as El Mirador (Hansen 2005), Tikal (Coe 1990), and Lamanai (Pendergast 1981), among many others, to become major players in administrative hierarchies on both the local and regional levels. Hereditary leadership, most likely in the form of divine kingship, developed by at least Late Preclassic times and paralleled trends toward population aggregation at large centers. Although the ultimate fates of various Preclassic centers different dramatically, the overarching trajectory of Maya lowland communities bent toward increasing population and land-use management. Greater levels of political organization were required to meet demands of increasingly dense and urbanized communities, and the development of more complex organizational structures is evident in the growth of civic centers and the clustering of centers in primary production areas.

2,000–1,400 Years Ago: Classic Maya civilization is marked by the continued growth of settlements and centers from the Late Preclassic through the Early Classic, with concomitant increases social complexity. Settlements expanded to all well-drained areas, especially the prime upland agricultural areas that compose 25 to 49 percent of the region (Bullard 1960; Fedick and Ford 1990), reflecting the intensification of land use. Monuments carved with hieroglyphic texts refer to warfare, and settlements began to spread to the less-optimal transitional wetland areas (Fedick 1989; Fedick and Ford 1990; Ford et al. 2009; McAnany 1995). Specialized production of distinctive elite and general household products also appears to have developed out of earlier, more generalized traditions of manufacture at this time.

1,400–1,100 Years Ago: The Late Classic, the apex of Maya civilization, includes the growth of civic centers and the proliferation of residential settlements (Culbert and Rice 1990). Most centers reached their maximum extent at this time. Tikal, for example, covered approximately 150 hectares of its center with monumental architecture (50 percent of the size of medieval London c. AD 1300). Large, dense settlements occupied all the well-drained ridges; the same areas initially occupied during Middle Preclassic population expansion (cf. Robin 2012). Competition among powerful Maya states increased, and stela references to warfare were prevalent across the Maya region, especially in southern Petén.

The Late Classic was also a time of ceramic diversification, with the sudden appearance of volcanic ash-tempered pottery in the fine wares (Ford and Rose 1995) and decaying ash in clay deposits. Specializations in products clearly separate into attached and entrepreneurial part-time occupations, as evident in the El Pilar center and settlement areas. Elite attached specialists around El Pilar produced artifacts made from exotic obsidian, and marginal farming areas primarily made utilitarian products.

While settlement counts are straightforward and well reported (see Robin 2012), and numbers of buildings have been used to indicate population size (Culbert and Rice 1990), actual population estimates are a source of major discord and debate. For example, Chase and others (2011), based on interpretations from Caracol, estimate regional population densities at 1,000 persons per square kilometer; while modeling at El Pilar, produced an estimated density of approximately 140 persons per square kilometer, a little more than one-eighth the projection for Caracol. In the Maya context, reasoned estimates of 100–200 persons per square kilometer are considered

viable (Culbert and Rice 1990); these numbers have yet to be reconciled with land use. Given the annual farming regime that calls for the use of temporary farmsteads (Zetina and Faust 2011), as well as the generational landscape strategies, archaeologist must distinguish primary from secondary residences to understand population distributions and estimate population density in relationship to available resources (compare Ford and Nigh 2015 to Lentz et al. 2015).

1,100–800 Years Ago: The last stela erected at Tikal (Stela 11 dated to AD 869) marks the end of Classic Maya civilization in the core of the Maya region. Power shifted northward to centers in modern-day Yucatan, Quintana Roo, and Campeche, Mexico, and away from the uplifted limestone ridge lands of central Petén. The period known as the Terminal Classic, a decline of construction and maintenance lasting several centuries, is visible in the abandonment of monumental structures and has been linked to droughts. The current leading hypothesis suggests the Terminal Classic collapse reflects an environmental transformation and attributes the cause to overpopulation, which resulted in extensive deforestation and soil degradation (Turner and Sabloff 2012). The main evidence cited for environmental change and drought comes from paleoecological records derived from lake sediments, although the interpretation of these data is ambiguous (Ford and Nigh 2015). The notion that there would be a cataclysmic environmental change because of human mismanagement and overuse of forest resources (Lentz et al. 2015) does not square well with the long trajectory of sustained growth nor the adaptations encountered at the time of Spanish contact (Farriss 1992; Terán and Rasmussen 2008).

800–500 Years Ago: The demise of the major Classic centers, such as Tikal and El Pilar, has been interpreted as the abandonment of the lowland interior. We know that public infrastructure – temples, palaces, and plazas – was not maintained and gradually succumbed to the elements. The neglect of public works speaks directly to the failure of the intricate Late Classic political economy, however, and not to the disappearance of farmers from the landscape. The Classic Maya regents' power to collect tribute and fund public projects clearly broke down, but the collapse of elite institutions does not imply a collapse of farming populations. That assumption is based on the notion that overpopulation and agricultural expansion drove deforestation beyond environmentally sustainable levels (Turner and Sabloff 2012; Webster 2002), which supposes that food production and forest are incompatible. The incompatibility of forest and field has yet to be demonstrated, however, and is contradicted by Spanish records that indicate successful adaptations by forest-dwelling Maya populations observed by the Spanish conquistadors 500 years ago.

The area between the sites of Tikal and Yaxhá shows continuous, undiminished occupation through the Terminal Classic (Ford 1986: 64–65). The El Pilar area, where excavations focused on residential units around monumental centers and beyond (Ford et al. 2009), shows that at least half of these units were occupied after the Late Classic. Areas without major public architecture, despite the demise of the centers, continued to flourish into Postclassic times (Alexander 2006; Robin 2012). Some large sites, such as Lamanai in northern Belize (Pendergast 1981), show continuous occupation from the Middle Preclassic to Spanish contact. Elite culture and power changed significantly at Lamanai during Terminal Classic and Postclassic times, but several decades of excavation have produced no evidence of a population collapse.

The abandonment of the temples, palaces, and plazas did not happen overnight, but was a gradual process that took decades and even centuries to complete (Webster 2002: 260–326). Only in rare instances of rapid site abandonment, such as has been proposed for Aguateca and other sites in the strife-riven Petexbatun area of southern Petén, would these processes play out within the lifetime of any one individual. First, portions of buildings would be left unmaintained, then entire architectural complexes would fall to abandonment, and

finally, no resources would remain for any maintenance at the site scale. (This is not unlike Detroit, where today more than 50 major private buildings, including banks, offices, theaters, and hotels, as well as many public buildings, such as libraries, schools, and even the central railroad station, have been abandoned. Some have been demolished for gardens.) Maya farmers, however, could very well have continued to live in their forest gardens that had been developed and maintained by their ancestors over several millennia.

Construction and maintenance of monumental architecture was a major issue in both the public and private sectors. Public construction was likely based on corvée labor provided by people who were also responsible for maintaining their own private structures. As corvée resources for public buildings diminished, private constructions correspondingly simplified. The Classic Maya signatures on the landscape dwindled; there was no more investment in stone quarries, and the minimum of maintenance on monuments was coupled with increasingly plain domestic structures. Farmers, freed from the burden of maintaining monumental architecture, organized into smaller units and farmed in the traditional way that was encountered at the time of the conquest (Farriss 1992; Jones 1998).

The Paleoenvironmental and Pollen Records

Paleoenvironmental reconstructions for the Maya lowlands rely primarily on lake core sediments from the central Petén area of Guatemala. Vegetation changes for the Holocene are recorded in the pollen register of these cores (e.g., Leyden 2002), which are dominated by wind-borne pollen and associated with deposits that reveal the influx of sediment by turbid currents into the lakes (Mueller et al. 2010). These lake layers are believed to correspond to widespread erosion that formed sedimentary "Maya clay" after deposition. The record of past precipitation is based on the concentration and ratios of the minor element titanium (Ti) and iron (Fe) in marine and lake sediments. Titanium and iron concentration is used as a proxy for rainfall, specifically summer monsoonal rain that is reflected in the annual sediment varves of cores from the Cariaco Basin off the coast of Venezuela (Haug et al. 2001) and corroborated in samples from the Petén Lakes. The overall interpretation of the paleoecological record has concentrated on a few pollen signatures that can misrepresent the evident diversity (Fig. 5). It is interesting to note, however, that even within the limited lens of the pollen data currently available, the simple interpretation that the forest gives way to savanna ecosystems during the Classic period is not borne out by the data. Pollen data do show that Ramon, or *Brosimum* pollen types, decrease as a fraction of all pollen types during Classic times, but there is no corresponding rise in the grasses that would define an increase in savanna-type environments (Figs. 5 and 6). Lumping disturbance and grass taxa together masks the true diversity revealed in the pollen record. The data demonstrate considerable diversity in the category of forbs, the same annuals and perennials that would be dominant in the open-crop component of the milpa cycle (Ford and Nigh 2015: 41–77).

8,000–4,000 Years Ago: High precipitation characterizes the Holocene Thermal Maximum in the Maya area. Plant communities changed from temperate to tropical, and *Brosimum*-type Moraceae pollen, interpreted as representing mature forest cover, became dominant in the pollen record. Temperate taxa, including pine and oak, maintain a presence but in low proportions (Leyden 2002).

4,000–3,000 Years Ago: The end of the Holocene Thermal Maximum was marked by more than 1,000 years of rapidly fluctuating precipitation. Although there were chaotic extremes of high and low annual rainfall averages, the trend was toward drier conditions that persist to the present (Haug et al. 2001). Amid this variable rainfall, the diversity of fossil pollen increased with the addition of wind-pollinated forbs and

The Maya, Fig. 5 Precipitation and select pollen over time in the Maya forest

The Maya, Fig. 6 Precipitation and select pollen for the last four millenia in the Maya forest

grasses. This increase in forb and grass pollen occurred relative to wind-pollinated trees coincided with the initial appearance of Maya clay (Mueller et al. 2010), which was interpreted as the result of local soil erosion into lakes and swamps.

3,000–2,000 Years Ago: Precipitation remained chaotic at the start of this period, but by 2,000 BP, rainfall stabilized under somewhat drier conditions, which are suggested by a decrease in titanium concentrations in the Cariaco core. The composition and relative abundance of pollen taxa in sediments hint at even greater species diversity, with forbs becoming dominant elements in the forested landscape. At the same time, Maya clay rose to its highest levels (Mueller et al. 2010: 1226), which has been interpreted to reflect erosion from agricultural deforestation but could result from some other environmental change, such as drier conditions or internal shifts within the lakebed itself (Mueller et al. 2010).

2,000–1,400 Years Ago: Precipitation stabilized at rates lower than those noted for the Holocene Thermal Maximum. The pollen record comprises stable vegetation that continues to be dominated by forbs and grasses, with less than 20 percent originating from forest taxa (using the *Brosimum*-type Moraceae as the forest proxy, Leyden 2002). Maya clay formation also stabilized at moderate levels (Mueller et al. 2010). In all, it is noteworthy that the paleoenvironmental data suggest steady continuity for this period.

1,400–1,100 Years Ago: There were few changes in pollen and sediment inputs at this time (see also Ford and Nigh 2015: 77–96), yet new data on precipitation suggest more variability in rainfall. Interpretations during this stable period in Maya prehistory continue to emphasize deforestation yet suggest that this unsustainable process began at least two millennia earlier (Turner and Sabloff 2012). A careful reading of the data, however, indicates continuity in the paleoenvironmental indicators: forbs make up the majority of the wind-pollinated pollen, with grasses and *Brosimum*-type Moraceae each making up less than one-fifth of the record.

1,100–800 Years Ago: No dramatic climatic changes have been resolved for this critical period of Maya prehistory, despite the search for evidence of drought and other environmental impacts. Precipitation was stable, with some rise in levels of titanium suggesting increased rainfall (Haug et al. 2001). Maya clay is present, grasses are registered, and forbs dominate vegetation; all this is interpreted as the result of continued deforestation, yet the complex matrix of the milpa-forest garden could account well for these facts.

800–500 Years Ago: The centuries leading up to the Spanish conquest show major shifts in pollen indicators, with the rise of *Brosimum*-type Moraceae and a drop in forbs. There is continuity in the grasses. Rainfall, as interpreted from the Cariaco Basin and Petén Lake cores, increased at this time, presumably improving annual farming conditions, especially in the dryer north. Yet these data have been interpreted as the rebounding of tree cover in the *absence* of farmers, which has hardly been proven. While the *Brosimum*-type Moraceae pollen does increase in the record, this likely marks a simple change in the *Brosimum* habitat. *Brosimum* is a vanguard pioneer plant, which is evident in its marker of the expansion of the tropics 8,000 years ago. The new habitat for *Brosimum* was most likely the result of collapsing temples and palaces, which provide an ideal habitat for Ramon. Population abandonment is also inconsistent with Cortés's observations at the time of the conquest. The so-called Classic Maya collapse lasted centuries (Webster 2002), and although the major centers ceased to be maintained, farmers could have simply stayed in their forest gardens.

An overview of the Maya chronology exalts the cultural developments but levies a charge of poor environmental management for the same acclaimed culture. Mesoamerica and the Maya forest today are a biodiverse conservation hotspot. With more than 24,000 plants, it is the most biodiverse tropical forest in the

Northern Hemisphere (Table 2). Dominated by plants that are useful to people (Table 3), it is evident that the Maya forest is a garden, a quality that could only be achieved by millennia of selection by human inhabitants. This conclusion has been debated (Lentz et al. 2015, Turner and Sabloff 2012) but can be corroborated by studies that show, from the tallest trees down to the smallest shrubs and herbs, the forest's qualities reflect uses that are still commonly known to the region's traditional farming families (Ross 2011). An examination of the milpa-forest garden cycle sheds light on the landscape of the Maya forest in the past and present.

The Maya, Table 2 Biodiversity of four continents

Region	Plant diversity
West Africa	9,000
Southeast Asia	12,000
Mesoamerica	24,000
Amazon	48,000

The Maya Milpa-Forest Garden Cycle: Landscape Correspondence

The adaptation and resilience of the forest garden-milpa cycle provides insight into an alternative explanation of Maya cultural and paleoenvironmental chronology. The milpa is the core of the innovative Maya forest garden, a system that developed over eight millennia of dwelling in a tropical forest environment. The foundations for milpa agriculture were created in Archaic times, and the flexible qualities that characterize the milpa cycle were developed during conditions of climate change. The milpa evolved as a sustaining system that was imminently conducive to intensified production based on skill and increasing labor input (Ford et al. 2009; Ford and Nigh 2015: 97–124). Adapted to the extremes of deluge and drought that dominated the millennium from 4,000 to 3,000 years ago, the system thrived in the Classic period at a time of relative precipitation stability and Maya civilization flourished.

The Maya, Table 3 Dominant plants of the Maya forest

Scientific name	Common name	Pollinator	Uses
Alseis yucatanensis	Wild mamey	Moths	Food
Aspidosperma cruentum	Malerio	Insects	Construction
Attalea cohune [a]	Corozo	Insects	Food
Brosimum alicastrum[a]	Ramon	Wind	Food
Bursera simarouba[a]	Chaca	Bees	Medicine
Cryosophila stauracantha	Escoba	Beetles	Production
Licania platypus	Succotz	Moths	Food
Lonchocarpus castilloi	Manchich	Insects	Construction
Manilkara zapota[a]	Chicle	Bats	Food
Piscidia piscipula	Jabin	Bees	Poison
Pouteria campechian	Zapotillo	Insects	Food
Pouteria reticulata	Zapote negro	Insects	Food
Sabal morrisiana[a]	Escoba	Insects	Production
Simira salvadorensi[a]	Palo colorado	Moths	Construction
Spondias radlkoferi	Jocote	Insects	Food
Swietenia macrophylla	Mahogany	Insects	Construction
Tabebuia rosea	Macuelizo	Bees	Construction
Talisia oliviformis[a]	Kinep	Bees	Food
Vitex gaumeri	Yaxnik	Bats	Construction
Zuelania guidonia	Tamay	Bees	Medicine

[a]Dominant in home gardens

The annual agricultural round and the milpa-forest garden cycle intimately adjusted to the annual drought. Resilient under extreme conditions, the only drought extreme enough to wreak havoc on the Maya coincided with the Spanish conquest. Known as the Little Ice Age, the droughts were more extreme than at any other time in the Holocene (Fig. 6). These droughts combined with the impositions of the Spanish to undermine Maya life ways spread famine across the northern Maya area. Effective to this day, the Maya milpa-forest garden cycle prevails as an adaptive and resilient strategy, recognized as the most diverse domestic food production system in the world (Campbell 2007).

The consequence of this interrelationship between the forest and the Maya is an anthropogenic landscape (Atran 1993) that resulted from generations of environmental management and was responsive to critical human needs during the precipitation chaos that marked the millennium after 4,000 years ago. The principal tool of the Maya forest garden is the Mesoamerican agrarian system commonly known as the milpa (Wilken 1987). The milpa is widely misunderstood but forms the axis of resilient Maya natural resource management systems (Terán and Rasmussen 2008).

The active gardens found around Maya forest villagers' homes show the diversity of the milpa as a domestic food production system. Even today, after the great Columbian Exchange that followed the Spanish conquest and the development of the global economy, Maya home gardens contain a bewildering array of fruits, wood, spices, fodder, medicine, ornamentals, and more. This inspiring evidence of selection and enrichment is a fundamental part of the forest and the adaptations of the Maya people to their environment.

Cycling from closed forest canopy to an open milpa, from a field of annual crops to an orchard garden, and from an orchard garden back to the closed canopy, the traditional Maya forest garden-milpa cycle builds resilience into the system of land use. All phases of the cycle receive careful human attention, and varying the input of labor and forest-succession management can be used to intensify production of desired products at every stage of the cycle.

The agroforestry management of the milpa cycle is initiated in closed-canopy forest when a clearing is opened with cutting tools and fire, the same level of technology possessed by the first inhabitants of the Americas. The first years in the milpa cycle involve annual cropping of fields, which are visually dominated by maize but include many companion crops selected from over 100 cultigens (Ford and Nigh 2015: Appendix I; Nations and Nigh 1980; Terán and Rasmussen 2008). The milpa includes its own ecology that deters pests, enhances soil nutrients, and maintains soil moisture. The selection of trees and bushes for succession begins before the end of the annual crops phase, and it is this intensity that determines the rate and floral composition of later phases. The Maya shape the forest to their needs and create the forest garden through acts of enrichment, selection, and planting in later phases of succession.

Each phase of the forest garden-milpa management cycle varies according the preferences and needs of the farmers (Table 4). The primary goal of producing food and household products is important in the initial clearing and planting phase as well as in the succeeding phases. The long-term sustainability is increased with each round of investment by managing soil properties to increase fertility and selecting a diverse range of useful plants to become part of the home economy. There is only one hot burn per cycle at the initial clearing of the milpa. Subsequently, judicious use of fire increases biochar content and guarantees fertility throughout the cycle. Managed natural regeneration includes selection of desirable species, and the exclusion of undesired plants, which alter the floral composition to favor plants valued by Maya farmers for household needs. At any given time in traditional Maya farming communities, less than 25% of cultivable land will be in the open annual crop phase, while other areas, once dedicated to milpa, will be under forest cover in managed stages of succession, emphasizing the wide variety of products needed including food, construction, medicine, materials, and more.

The Maya, Table 4 Dominant plants of the milpa-forest garden cycle from the Maya forest[a]

Milpa cycle	Dominant plants (Wind-pollinated spp. indicated in bold)
Open multi-crop maize field ~ favoring sun Phase 1 initialization (1–4 years)	Cultigens: ~99 spp. such as *Capsicum* spp., ***Chenopodium ambrosioides* L.**, *Cnidoscolus* spp., *Cucurbita* spp., ***Lycopersicon esculentum* Mill.**, *Phaseolus* spp., *Xanthosoma yucatanense* Engl., ***Zea mays* L.** Several other genera found in Leguminosae Non-cultigens**:** ***Ambrosia* spp.**, ***Cecropia* sp.**, ***Mimosa* sp.**, ***Trema* sp.**, and several genera found in **Amaranthaceae, Asteraceae, Cyperaceae, Euphorbiaceae, Melastomataceae, Poaceae, Urticaceae**
Long-lived perennial reforestation ~ producing shade Phase 2 renewal cycle (4–12 years)	*Acacia cornigera* L. Wild, *Ananas comosus* L. Merr., *Annona muricata* L., *Attalea cohune* C., ***Brosimum alicastrum* Sw**., *Bucida buceras* L., *Cucurbita pepo* L., ***Bursera simaruba* L.**, *Byrsonima crassifolia* L. Closed canopy ~ favoring shade Phase 3 culmination (>12 years)	*Alseis yucatanensis* Standley, *Aspidosperma cruentum* Woodson, *Attalea cohune* C. Mart, ***Brosimum alicastrum* Sw**, *Bursera simarouba* L.,*Cryosophila stauracantha* Heynh. R. Evans, *Licania platypus* Hemsley Fritsch, *Lonchocarpus castilloi* Standley, *Manilkara zapota* L. van Royen, *Piscidia piscipula* L. Sarg, *Pouteria campechiana* Kunth Baehni, *Pouteria reticulata* Engl., *Sabal morrisiana* Bartlett, *Simira salvadorensis* Standl, *Spondias mombin L.*, *Swietenia macrophylla* King, *Talisia oliviformis* Radlk, *Vitex gaumeri* Greenman, *Zuelania guidonia* Britton & Mill sp.

Note: Phase 1 is dominated by wind-pollinated taxa, and Phase 3 is dominated by biotically pollinated taxa
[a]Only native taxa are included. Based on Campbell et al. (2006). Bolded taxa are wind-pollinated taxa

The dynamic result of this agricultural cycle is a resilient system that builds a diversified mosaic landscape. Useful plants dominate the milpa and are encouraged to flourish in the successive forest stages managed by Maya farmers. This flexible and adaptive system coevolved with the development of the tropical forest in the Archaic, when the ancestral Maya became familiar with their landscape and the forest resources it could provide. The origins of this system lie in early adaptations to predictably warm and wet climate during the Holocene Thermal Maximum from 8,000 to 4,000 years ago. System resilience was creatively developed during the chaotic and unpredictable climates that characterized the Preclassic after 4,000 years ago. Evolved to mitigate both deluge and drought, the resulting system was an innovative adaptation that manages land cover, soil development, water and moisture, biodiversity, and forest products fundamental for livelihoods. The forest garden-milpa cycle is both flexible and sustainable and has served contemporary Maya farmers much as it did their ancestors for millennia. The prosperity of the Classic period speaks directly to the success of this system and the ingenuity of the culture that invented it.

The Fundamentals

The agricultural civilization of the Maya emerged naturally within the context of the Maya forest and the tropical lowland ecosystem of southern Mexico's Yucatan Peninsula, Petén of Guatemala, and Belize (cf. Conklin 1957). These forests were

once considered pristine, but as we know now, they constitute a highly structured and managed environment. Geographers and botanists now recognize that humans, over the course of millennia, have influenced the vegetation of the Maya forest through intervention in processes of ecological succession. Human impact on the forest today is largely expressed through European practices of cattle pasture and plowing, which together threaten the integrity and biodiversity of this important natural resource. In many respects, the population-deforestation relationship playing out in the Maya forest now is exactly what has been said to have happened a thousand years ago. But how can that be, if there were no sheep, cattle, or plows during the period in question?

Despite broad recognition of human impacts on the Maya forest by scholars, they disagree on the timing and nature of these impacts. Turner and Sabloff (2012), summarizing current interpretations of received wisdom, posit that lowland Maya interactions with the forest culminated in expanded clearing for agricultural fields and were so environmentally destructive that they caused the collapse of Classic Maya civilization in the ninth century. This interpretation is in line with Webster's (2002) conclusion that the Maya are reenacting the same story today. He implies that the milpa system is at the root of contemporary threats, but he refers to satellite imagery that clearly exposes the expansion of cattle pasturage, *not* milpa farming (Brook and Knudsen 2014). While most studies of the Maya assume that the collapse of the civilization was related to deforestation by people, the Maya forest today is known for its diversity and abundance of useful plants that remain as beneficial now as they were in the past.

Amid the expansion of "conventional" monoculture cropping based on European agricultural production founded on the plow, the traditional Maya farmers continue to practice hand cultivation based on local ecological knowledge. What is behind the historical ecological transformation of the Maya forest? How can the prehistory of the Maya people provide the background for understanding this transformation? Where are the lessons to be learned? How can we build on the inherent values of local knowledge for incorporation into our future adaptations? These questions clearly need to be considered if archaeology is to shed any light on the conservation challenges we face today.

McBryde, Isabel

Sharon Sullivan
Nymboida, NSW, Australia

Basic Biographical Information

Isabel McBryde is an Australian archaeologist. She was educated at the Presbyterian Lady's College, East Melbourne, and at Melbourne University, graduating with honors in 1957. In 1957, she was awarded a postgraduate scholarship, and in 1958 held a temporary lectureship at the University of New England. In 1959, she won the Jessie Webb Scholarship which enabled her to study at the British School in Athens after gaining a Diploma in Prehistoric Archaeology from Cambridge. In 1960, she graduated with an M.-A. Honors (I) in the School of Classical Studies, University of Melbourne.

From 1960 to 1973, Isabel was in turn the first Lecturer, Senior Lecturer, and Associate Professor in Charge of Prehistory, University of New England. She established courses in prehistory at all levels, and initiated and directed a groundbreaking program of regional research in archaeology and ethnohistory in northern New South Wales, with student field training. In 1967, she was awarded a Ph.D. by this University.

From 1974 to 1994, she was in turn Senior Lecturer, Reader, and Professor of Archaeology, at the Department of Archaeology and Anthropology, The Faculties, Australian National University, where she continued her extensive research, taught and mentored many students, and actively promoted links between Archaeologists and Indigenous people including the entry of Indigenous students into archaeology.

In 1994, Isabel retired from the university with the title of Professor Emerita and is a School Visitor in the History Program in the Research School of Social Sciences and a Visiting Fellow in the School of Archaeology and Anthropology at the Australian National University.

Throughout the course of her busy and fruitful academic career, Isabel has also been very active in a range of national and other seminal committees and boards and in doing so, she played a very significant role in the development of archaeology and cultural heritage management in Australia. Some of her most important roles included being a Member of the Prehistory Advisory Committee, Australian Institute of Aboriginal Studies, from 1964 to 1976, Member and sometimes Chair of Aboriginal Relics Advisory and then of the Interim Aboriginal Sites Advisory Committee (National Parks and Wildlife Service NSW) from 1970 to 1985, and Member, NSW Aboriginal Cultural Heritage Interim Committee (NSW NPWS and NSW State Land Council) 1993–1996, a member of Council of the Australian Academy of the Humanities from 1981 to 1983, a Commissioner of the Australian Heritage Commission from 1982 to 1988, in turn member of the Consultative Committee on the Plan of Management, of the Subcommittee on Research and of the Technical and Scientific Advisory Committee – Willandra Lakes Region World Heritage Area between 1984 and 1998, a member of the Advisory Committee to the Aboriginal Liaison Officer and Aboriginal Students Centre and then member, of the Australian National University's Consultative Committee on Aboriginal Education, 1987–1998, and member of the Board of Management of Uluru/Kata Tjuta National Park, 1996–2001.

Major Accomplishments

Isabel McBryde is a founder of the discipline of archaeology in Australia, and a significant proponent and practitioner of archaeology as multifaceted, and multidisciplinary with a contemporary social relevance. She has a deep commitment to the responsibilities which this brings. Her pioneering work has contributed immensely to Australian archaeology as we know it today (Macfarlane et al. 2005).

There was no precedent for her earliest research work in Australia. In contrast to many of her colleagues who limited their research to the excavation of promising sites, Isabel undertook a regional study of northern New South Wales which encompassed all types of site patterns and their distribution, ethnographic work, linguistics, geography, museum studies, and environmental zonation, followed by excavations informed by this detailed regional research. This rich, multifaceted regional work, its involvement of locals, and its fine-grained study of an astonishing range of evidence, all made it a model for Australian archaeological studies and gives us a seldom achieved picture of the Aboriginal presence in and cultural adaptation to the landscapes of northern New South Wales (McBryde 1974, 1978). Other spin-offs from this work include her meticulous and exemplary studies of early photographs of Aboriginal people, of first settler reminiscences, and of Australian Aboriginal ethnographic specimens from across the world located, provenanced, documented, and interpreted by her during her many international study tours (Macfarlane et al. 2005). Her early petrological work with R.A. Binns was also the first of its kind in Australia and a landmark publication (Binns and McBryde 1972). She is a national and international leader in studies of the social meaning and context of artifacts. A multifaceted approach to fieldwork also characterized her work with stone artifacts, quarries, and with trade and exchange networks. In this work, she traced and explained for the first time the dynamics and social determinants of these networks and in doing so gave story and meaning back to the Australian landscape (see, for instance, McBryde 1984, 1997, 2000).

Landscape has been of particular concern for Isabel – especially the landscape of hunter-gatherers which she has actively and influentially promoted nationally and internationally through her writing, her involvement in the cultural landscape of World Heritage Areas, and her guidance in landscape management generally.

Isabel has been an important agent in early work in cultural heritage conservation generally. Historic, natural, and Aboriginal heritage, all received her attention through the wide

range of committees and boards where she was an active participant and seminal contributor.

Isabel involved local Aboriginal people in her 1975 excavations at Lake Arumpo, now part of the Willandra Lakes Region World Heritage Area (Macfarlane et al. 2005). This was symptomatic of a key theme of her research and teaching, which emerged early – the rights of Aboriginal people to the custodianship of their heritage, including their right to a decisive voice in archaeological research in Australia (See, for example, McBryde 1985 and 1986). She has written about, lobbied for, and actively promoted this position, sometimes in difficult and contentious circumstances. She has been very influential in the rapprochement and cooperation between Aboriginal people and archaeologists which with some exceptions has come to characterize Australian archaeology. Her leadership at the Australian National University produced outstanding success in training young Aboriginal people as archaeologists (Macfarlane et al. 2005).

Isabel's contribution to archaeology and cultural heritage management has been nationally recognized. In 1990, she became an Officer of the Order of Australia and received a D. Litt. (*hon. causa*) from the University of New England in 1992. In 2003, she received a Centenary medal, and was awarded the Rhys Jones Medal – the Australian Archaeological Association's highest award. She has been awarded Honorary Life Memberships by the Australian Archaeological Association, Australia ICOMOS, and the Canberra Archaeological Society.

McCarthy, Frederick D.

Shaun Joseph Adams
Australian Research Centre for Human Evolution, Griffith University, Nathan, Queensland, Australia
Quandamooka Yooloburabee Aboriginal Corporation, Stradbroke Island, Queensland, Australia

Basic Biographical Information

Fred McCarthy was a pioneering Australian archaeologist/anthropologist throughout the

twentieth century. He was born in 1906 in Petersham, Sydney. At the age of fourteen, McCarthy left schooling and took a position as a library clerk at the Australian Museum, Sydney. In 1930 McCarthy was transferred to the Department of Birds and Reptiles where he stayed for 18 months (Kahn 1993). In 1931 he produced his first research paper, "Lake Burrill and How Our Coastal Lakes Were Formed" (McCarthy 1931). In 1932 McCarthy was offered a position as Assistant Curator of Anthropology under W.W. Thorpe (Khan 1993). Thorpe died within months of taking the position and subsequently McCarthy took over curatorship of the entire anthropology collection. In 1933 McCarthy enrolled at Sydney University and undertook a Diploma of Anthropology under Professor A. P. Elkin. His first published excavation was on a rockshelter near Emu Plains in 1934. In 1935 his thesis, *The Material Culture of Eastern Australia. A Study of Factors Entering into Its Composition*, was accepted by Sydney University. Fred McCarthy and his future wife, Elsie Bramell, were the first university-trained anthropologists employed at the Australian Museum to manage the anthropology collections.

Between 1935 and 1936 McCarthy and C.C. Towel undertook excavation at Lapstone Creek in New South Wales. It was the first site in New South Wales in which culture periods were defined on the basis of stratigraphy (McCarthy 1948; Kahn 1993). Other fieldwork conducted throughout McCarthy's career covered areas such as the New South Wales east coast, western New South Wales, Arnhem Land in Northern Territory, Cape York in Queensland, and northwest Western Australia. Throughout these regions McCarthy undertook excavations, the recording of rock art, and ethnographic studies (Attenbrow 1998).

In 1938 McCarthy attended the Third Congress of Prehistorians of the Far East in Singapore with Norman Tindale and Dermot Casey (McBryde 1998). Here he presented a paper on observed relationships between Australian and Indonesian stone implements (McCarthy 1938a). This trip heralded a new era for McCarthy and on his return he began to press for the drafting of legislation to protect Aboriginal sites in New South Wales (McCarthy 1938b: 120–6). In 1946 McCarthy coauthored one of his best known works, *The Stone Implements of Australia*, with Bramell and Noone. In this volume they attempted the first systematic typological classification of Australian stone tools (McCarthy et al. 1946; Attenbrow 1998).

In 1948 McCarthy joined the Australian-American Scientific Expedition to Arnhem Land under the leadership of C. P. Mountford. Over 9 months McCarthy worked with Frank Setzler and Margaret McArthur conducting excavation and observing many aspects of Aboriginal life (Attenbrow 1998). McCarthy's work on food quest time factors was written with McArthur and remains a classic reference today (McCarthy and McArthur 1960). Throughout 1958 McCarthy studied rock art in north Western Australia and central-west New South Wales. In 1961 he also recorded totemic dances at Aurukun in north Queensland (Khan 1993).

In 1961 experts from many disciplines associated with Australian Aboriginal studies met at a research conference to discuss the founding of an institute for Aboriginal studies (Sheils 1963). McCarthy contributed through his knowledge of archaeology and material culture, and by the end of the meeting, an interim council had been appointed (Sheils 1963: 52–6, 171–94). By 1964 McCarthy was appointed as the Foundation Principal of the Australian Institute of Aboriginal Studies, now known as the Australian Institute of Aboriginal and Torres Strait Islander Studies (AIAS Newsletter 1965: 1). He served as the principal of the institute until his retirement in 1971. McCarthy continued research into Aboriginal studies until his death in 1997.

Major Accomplishments

McCarthy's excavations at Lapstone (1935–1936) and Capertee (1958–1961) produced stratified stone artifact sequences that formed the basis for

his famous Eastern Regional Sequence (McCarthy 1948, 1964). This sequence consisted of three phases: Eloueran, Bondaian, and Capertian. Although regional variants were later found and Mulvaney promoted two pan-continental phases, McCarthy's tripartite sequence remains relevant today (Attenbrow 1998). In 1946 McCarthy, Bramell, and Noone published *The Stone Implements of Australia*, which was later revised and published as a book in 1976. This groundbreaking work attempted the first continent-wide typological classification of Australian stone artifacts.

McCarthy recorded many styles of rock art throughout Australia. His recordings of the Sydney-Hawkesbury sandstone region remain the only detailed documentation for many sites in this region and an invaluable source of information. Between 1958 and 1979 volumes of *Australian Aboriginal Rock Art* were published by the Australian Museum. It covered regional variants across Australia for engraved and pigmented sites and attempted to find a temporal sequence of styles (Attenbrow 1998). His final work *Artists of the Sandstone* contains ethnohistorical records of Aboriginal life in the Sydney area and is incredible for its wealth of knowledge and consistency.

McCarthy was pivotal in changing the focus of Australian Aboriginal exhibitions at the Australian Museum to encompass social, religious, and economic aspects of culture. He also established and maintained a catalogue of Australia wide sites with the Institute (AIATSIS). As early as 1938 he was drafting proposals to create legislation for protection of Australian Aboriginal sites.

In 1980 the Australian National University granted McCarthy an Honorary Doctorate of Sciences for his vast contribution to anthropological research in Australia. In 1990 he was made a fellow of the Australian Academy of the Humanities and in 1993 the Australian Museum devoted papers by contemporary researchers to commemorate his groundbreaking studies. That same year the Australian Archaeological Association conference in Darwin and its publications were dedicated to Fred McCarthy.

Fred McCarthy published more than 300 papers throughout his life and was pivotal to our contemporary understandings of Aboriginal studies. Over his career he paved the way for more ethical research and helped incorporate Aboriginal people into the decision-making processes around the recording and preserving of their culture.

McDonald, Josephine J., Fig. 1 Jo McDonald at UWA event in 2012. (Photo: UWA Press)

McDonald, Josephine J.

Peter Veth
Oceans Institute, University of Western Australia, Crawley, WA, Australia

Basic Biographical Information

Jo McDonald (Fig. 1) was born on the 23 October 1960. She grew up in Cronulla and attended Burraneer Bay Primary School and Woolooware High School with her brother and sister. She undertook her undergraduate training in the Department of Prehistory and Anthropology at the University of Sydney. John Clegg was an early influence, and her honors research investigated whether species differentiation in kangaroo's feet could account for stylistic variability in engraved kangaroo tracks. This study was based at Sturt's Meadows, a semiarid Panaramitee style (Maynard 1979) engraving site in western New South Wales. She graduated with honors in 1982 – and embraced cultural heritage management for the next 5 years – working with many consultants in the Sydney region and forming the company Brayshaw McDonald Pty Ltd., with colleague Helen Brayshaw. She began a regional management study on Sydney Basin rock art for the National Parks and Wildlife Service, which after 3 years morphed into her Ph.D. research.

Her Ph.D. was completed at the Australian National University, where Andree Rosenfeld was her supervisor. The Sydney region's dual-media rock art (pictographs and petroglyphs) is one of the only in Australia where there are two contemporaneous art systems operating throughout the Holocene. After completing her Ph.D., McDonald continued to work in cultural heritage and for 15 years was the Managing Director of one of Australia's best-practice research-driven cultural heritage management consultancy companies – Jo McDonald Cultural Heritage Management (http://www.jo-mcdonaldchm.com.au/).

She has been involved in the development of the Australian Association of Consulting Archaeologists Inc. (AACAI), holding at various times the position of President, Membership Secretary, Secretary, and NEC member. She was made a Life Member of AACAI in 2010. She was President of the Australian Archaeological Association in 1997–1998.

After moving to Canberra in 2003 with her partner Peter Veth, she continued to manage this company while becoming more research active in rock art. McDonald was Principal Investigator with professors Howard Morphy and Peter Veth on the $1.2mill ARC Linkage Project – Canning Stock Route Project – Rock Art and Jukurrpa. JMcD CHM was an industry partner on this Linkage Project. This project, which grew from Aboriginal community concerns about the burgeoning tourist impacts along this 1,800 km transect through Western Australia's sandy deserts, provided significant research outcomes as well as baseline data for a Plan of Management and a governance structure for the Aboriginal communities located across the arid zone.

In 2011, Jo McDonald commenced an ARC Future Fellowship, with a project studying rock art's role in the settlement and occupation of the arid zone (comparing the Western Desert in Australia with the Great Basin, USA) (Fig. 2). In 2012, she became the inaugural (endowed) Rio Tinto Chair of Rock Art Studies at UWA. She is the Director of the Centre for Rock Art Research + Management (CRARM) at UWA.

She has three children from her marriage to Neil Hanson (Oliver, Jesse, and Zoe). Five of the seven children she and Peter have, have finished school in the last 7 years.

McDonald, Josephine J., Fig. 2 Jo McDonald recording rock art in the Carnarvon Ranges, Western Desert in 2012. (Photo: Stafford Smith)

Major Accomplishments

Over three decades of practice, Jo McDonald has bridged the gap between academia and public archaeology, as well as working towards a mainstreaming of rock art research in archaeological context. Significant contributions to Australian archaeological practice have been through CHM as well as rock art research. Over two decades, McDonald developed conservation and management strategies for the fast-disappearing indigenous cultural heritage resources of Sydney being continually impacted by urban development. She has excavated more than 80 open sites on the Cumberland Plain and rockshelters in the surrounding sandstone country and developed the theoretical and predictive basis for open-site archaeology with a focus on landscape sampling, lithic analysis, and the discovery of sites in an aggrading geomorphic landscape (where the archaeological evidence is invisible/buried in the topsoil). As a result, the industry standard for open-area excavation is now >100 sq. m per site and focussed on cultural landscapes and the retrieval of complete lithic assemblages (JMcD CHM 2005; White and McDonald 2010). Nowhere else in Australia has this extent of open-site archaeology been achieved with obvious research implications for urban/mining contexts around the country.

Major contributions have included:

- The development of appropriate best-practice standards in the sampling, excavation, and analysis of open sites.
- The excavation of the oldest Aboriginal site in the Sydney region – a 30,000-year-old open site in a sand body in Parramatta. More than

500 sq. m of this significant landscape have been salvaged prior to development.

- Working with the police on several forensic excavations (e.g., McDonald 1992). This work (with physical anthropologist, Dr Denise Donlon) resulted in the development of an archaeological unit within the Forensic Diploma which was taught by the NSW Police Department to its Crime Scene officers.
- The discovery, excavation, and collaborative analysis of the first Australian evidence for death by spearing of the *Narrabeen Man* – found beneath a bus shelter during installation of infrastructure (McDonald et al. 2007; JMcD CHM 2008).

Her Ph.D. research on the rock art of Sydney was contextualized by the archaeological excavations undertaken in a number of shelter art sites (McDonald 2008). This work demonstrated the contemporaneity of rock art production with other occupation evidence. Her Ph.D. research achieved some of the first radiocarbon direct dates on pigment rock art anywhere in the world (McDonald et al. 1990).

McDonald's contributions to rock art research have been theoretical and management oriented. Her Ph.D. was the first in the world to undertake a regional analysis of a dual-media rock art province and contextualize this using information exchange theory (Wobst 1977). As well as writing Plans of Management for specific rock art sites and developing a management basis for art sites in the Sydney region, she has pioneered the use of applied rock art research in several successful Native Title claims (De Rose Hill, Martu, and Birriliburu). Following her early dating work in Sydney, she has undertaken with colleagues an intensive program of pigment dating in the Western Desert, on the Canning Stock Route Project. She has also used rock art research to demonstrate the scientific significance of rock art across the Dampier Archipelago in support of National Heritage listing, achieved in 2007. This work, completed with Peter Veth, has more recently been supplemented by a study of this art province's Outstanding Universal Values for UNESCO World Heritage List nomination. She has also worked with the Department of Indigenous Affairs on developing a Heritage Inventory methodology to progress the documentation of the rock art across this art province (JMcD CHM 2008, 2009b).

She has recently co-edited a new international volume designed as a textbook for rock art scholars (McDonald and Veth 2012; and see McDonald 2013). She is currently working with colleagues to develop digital recording techniques, database development, and GPS-linked techniques to enable rock art research to be managed as digital heritage.

McGimsey III, Charles R.

Thomas J. Green
Arkansas Archaeological Survey, Fayetteville, AR, USA

Basic Biographical Information

Charles R. McGimsey, III (1925–2015), known as Bob to all who know him, was one of the pioneering figures in the development of CRM in the United States. His numerous publications and lectures called attention for the need of archaeologists to engage the public for both financial support and the protection of archaeological resources. He was the driving force in the development and passage of state and national legislation for the management and protection of archaeological resources, including the establishment of the Arkansas Archaeological Survey. He led the effort to professionalize archaeologists in the United States with the creation of the Society of Professional Archaeologists, now the Register of Professional Archaeologists.

His early training in archaeology was interrupted by World War II. He finished his undergraduate degree at the University of New Mexico in 1949 and took his Ph.D. at Harvard University in 1958. His dissertation research focused on the Southwest, and he conducted extensive research in Panama during the 1950s and early 1960s. In 1957, he was hired as the assistant curator and assistant professor at the University of Arkansas. He was a founding member of the Arkansas Archaeological Society, a statewide amateur organization established in 1960. From 1960 to 1983, he was Director of the University of Arkansas Museum. He helped create the Department of Anthropology in 1969 and was the initial chair until 1972. In 1967, he was also named the Director of the Arkansas Archaeological Survey, a position he held until his retirement in 1990.

Major Accomplishments

Bob was responsible for two influential publications during the early development of CRM in the United States. One, *Stewards of the Past* (1970) cowritten with Hester A. Davis and Carl Chapman, grew out of concern for massive site destruction from agricultural practices in the Mississippi River Valley. This small pamphlet was an early manifesto for the preservation of the archaeological record and the engagement of the public. It called on everyone to be a steward of this nonrenewable resource. Thousands of copies were distributed free. In 1972, as an outgrowth of gathering information on state programs, the book *Public Archaeology* detailed his vision for the engagement of professional archaeologists with the general public. It was an inspiring call for archaeologists to engage the public to develop state laws, to nurture amateur archaeological societies, and to develop public programs.

His legacy in the legal arena began at the state level. In 1959, he drafted and successfully lobbied for legislation establishing a program for archaeological research in Arkansas based in the University Museum. In 1967, working with the Arkansas Archaeological Society, he expanded the 1959 law and created the Arkansas Archaeological Survey. Also in 1967, he was responsible for legislation making it illegal to damage and destroy archaeological sites on public lands in Arkansas and requiring state agencies and municipalities to cooperate with the Arkansas Archaeological Survey. In 1977, he helped draft the legislation establishing Arkansas's state historic preservation office.

At the national level, he was most associated with Public Law 93–291, the Archaeological and Historic Preservation Act of 1974. As President of the Society for American Archaeology, he wrote much of the law and spent endless hours lobbying Congress for its passage. The law is significant in that it authorizes federal agencies in the United States to spend project funds on site preservation. It complements Section 106 of the 1966 National Historic Preservation Act by requiring data recovery of properties that will be destroyed by federal projects.

In addition to his legislative efforts, while President-elect and President of SAA, Bob traveled extensively giving lectures and participating in meetings and symposia of various national organizations while arguing the value of public archaeology. Most importantly, he and Hester Davis organized the Airlie House Seminars in 1974 that gathered prominent academic, federal, and state archaeologists and Native Americans to discuss major issues in the developing CRM field. Separate seminars provided recommendations on professional qualifications, report standards, management, communication with the public, laws and regulations, and Native American issues (McGimsey and Davis 1977). The report was quite influential during a critical period of CRM development as it provided guidance to many individuals developing federal and state programs in response to national legislation. As an outgrowth of the Airlie House Seminars, McGimsey argued vehemently for standards to judge the professional capability of archaeologists. He was a founding member and advocate for the Society of Professional Archaeologists, now the Register of Professional Archaeologists, and was its President in 1984. Throughout his career, he wrote and commented extensively on CRM matters (McGimsey 2004).

The Arkansas Archaeological Survey was established by the Arkansas General Assembly in 1967. While McGimsey credited members of the Arkansas Archaeological Society for the legislative clout to affect passage, the design of the Arkansas Archaeological Survey was his alone. The Survey is an independent unit of the University of Arkansas System with 11 research stations associated with state universities and state archaeological parks with a central coordinating office. It follows his vision of public archaeology by working closely with amateurs and the general public in a program of archaeological research, preservation, and education. The Survey and the Society annually sponsor an archaeological training program for amateurs and the general public. The unique organization of the Survey has been a model for other state programs in the United States.

McGimsey III, Charles R., Fig. 1 Arkansas Archeological Survey

He received many awards honoring his career. The SAA awarded him the first Distinguished Service Award in 1975 and again in 1995 the Award for Excellence in CRM. In 1989, the Arkansas Archaeological Society named its highest award after him to honor those with distinctive records of archaeological site preservation. Charles R. McGimsey died on January 20, 2015 (Fig. 1).

McGrail, Seán

Joe Flatman
English Heritage, London, UK

Basic Biographical Information

Born in 1928, Seán McGrail is currently Visiting Professor of Maritime Archaeology at the University of Southampton (1991 onwards). Prior to that time, he held positions at the University of Oxford (1986–1993) and the National Maritime Museum, Greenwich (1976–1986). He is one of the most distinguished British nautical archaeologists, with a long history of research and publication in the field dating back to the mid-1970s. He was instrumental to the development of maritime archaeology as a formal academic discipline, and many of his publications remain the key reference works for the subject. Prior to his career in archaeology, he served in the Royal Navy (1946–1968), including seeing active service during the Korean War, particularly as a pilot in the Navy Fleet Air Arm, before studying archaeology at the Universities of Bristol (1968–1971) and London (1972–1978).

Major Accomplishments

McGrail's major accomplishments focus on two distinct but related concerns: firstly, nautical archaeology, especially studies of ship technology, and secondly, maritime archaeology, especially the development of maritime archaeology as a formal academic discipline and teaching specialism (his 1984 work *Aspects of Maritime Archaeology and Ethnography* being particularly influential in this respect). In both concerns, he has played an active leadership role since the 1970s, including editing many of the key works on both subjects and playing a major role in related organizations, including notably the UK's Advisory Committee on Historic Wreck Sites (1974–1998) and the International Symposia on Boat and Ship Archaeology (ISBSA) that have been held periodically since 1976. McGrail was

also central to the establishment of key organizations in maritime archaeology, for example, the Centre for Maritime Archaeology at the University of Southampton, currently the lead academic institution for maritime archaeology in the UK.

McGrail's major publications reflect his focus on nautical archaeology, especially the analysis of ship technology through the rigorous application analytical rules leading to the understanding of shipbuilding traditions. Commencing with his (1978) *Logboats of England and Wales*, he has consistently led this field of study in the UK in particular and more generally internationally, especially in North West Europe. The seminal work in this field remains in McGrail's 1987 (reissued 1998) *Ancient Boats in North West Europe*, a theme that he expanded on in his majestic, encyclopedic (2001) *Boats of the World*. His work has included international fieldwork, in particular in South East Asia (see McGrail et al. 2002), but has primarily been focused on North West Europe, particularly on Romano-Celtic and Medieval vessel technologies, for example, his joint analysis (with Nigel Nayling) in 2004 of the Barland's Farm Romano-Celtic Boat. Other significant vessel assemblages that he has been involved in analyzing include the Late Bronze Age "raft" from Brigg, Lincolnshire; the Viking Age vessel finds from Wood Quay, Dublin; the mid-thirteenth century CE boat from Magor Pill, South Wales; and the mid-fifteenth century CE ship from Newport, South Wales. His work has also included the publication of popular books on this subject, notably his (1981) *The Ship*.

The influence of Seán McGrail can perhaps too easily be underestimated by those from outside the specialized subdiscipline of maritime archaeology. A self-effacing man, he has quietly and unostentatiously taught and mentored generations of maritime archaeologists working around the globe. His emphasis on rigorous analytical inquiry into boat and ship technologies helped make the UK a center of excellence in maritime archaeology in the 1980s when the nation was at risk from being eclipsed in this respect by other nations, including neighbors like Denmark and "distant cousins" like Australia. Internationally, there is a strong case to be made that our global understanding of ancient ship technology would be at least a decade behind the present-day without his contributions (see McGrail 1997 for a summary of his work).

Meadowcroft: Geography and Culture

J. M. Adovasio
Harbor Branch Oceanographic Institute, Florida Atlantic University, Fort Pierce, FL, USA
Senator John Heinz History Center, Pittsburgh, PA, USA

Introduction

Since the initial publication of the first radiocarbon sequence for Meadowcroft Rockshelter (Adovasio et al. 1975), this site has been among the most controversial localities advanced for early human occupancy of the New World. The reasons for Meadowcroft's persistently and initially contentious status are ultimately reducible to a single factor – Meadowcroft Rockshelter was the first archaeological locality to seriously challenge the then long-prevailing paradigm that the peopling of the New World was the singular accomplishment of the makers of Clovis fluted projectile points or their immediate precursors.

While Meadowcroft would not be the first site to actually break the Clovis-first barrier (that distinction is almost universally attributed to Monte Verde in Chile), it *did* set the stage for the collapse of that nearly sacrosanct chronological boundary. Additionally, unlike most of the 500 or so other claimants to pre-Clovis status, Meadowcroft Rockshelter was universally acknowledged even by its critics as "the most carefully excavated and extensively documented site in North America" (Custer 1996: 92) and as a "model for Paleo Indian studies" (Fagan 1990). Although, as many have pointed out, there is, as yet, no final report on Meadowcroft, there is a very extensive literature (Adovasio et al. 1975, 1977, 1978, 1979–1980a, 1979–1980b, 1984, 1985, 1988, 1990, 1998; Adovasio and Page 2002; Adovasio and Pedler 2013, 2016; Carlisle and Adovasio 1982; Carr and Adovasio 2002) and an extremely consistent, multiple assay radiocarbon chronology. In short, Meadowcroft Rockshelter does not exhibit the same acceptance-related difficulties as Pedra Furada, Pendejo Cave, Topper, or any of the other alleged early localities discussed and then summarily dismissed by an understandably skeptical North American archaeological community. As discussed further below, while debate still exists about the chronology of the earliest anthropogenic visitation/use of Meadowcroft, most former critics or ambivalent observers now conclude, to quote one of them, that "whatever the precise date of first occupation, Meadowcroft is one of the earliest well-documented sites in North America" (Fagan 1995: 80).

History of Research

Meadowcroft Rockshelter was discovered in 1955 by the late A. Miller, a local southwestern Pennsylvania landowner, amateur archaeologist, and historian whose family had owned the Meadowcroft property since the mid-1790s. Miller attempted to elicit professional interest in the site while, at the same time, protecting it from pot-hunting and vandalism. His efforts and those of friend and colleague, P. Jack (then of California State College in California, Pennsylvania), to secure professional assistance were unsuccessful until 1973 when the author initiated excavations in June of that year. Thereafter, extensive excavations were conducted from 1974 through 1978 and at widely separated times in the 1980s, 1990s, and most recently in 2011. The analyses of materials from the site are ongoing.

In early 2008, the site – by then named a National Historic Landmark and Commonwealth Treasure – became accessible to the public with the construction of an architectural elaborate enclosure and observation deck. The site is now owned and operated by the Senator John Heinz History Center in Pittsburgh, Pennsylvania, which also maintains a living museum of nineteenth-century rural life and a replicated sixteenth-century Native American village on the hilltop above the rock-shelter.

The excavation and attendant analyses at Meadowcroft Rockshelter were – and still are – the epicenter of a much larger project designed to study the entire contiguous Cross Creek drainage

both before, during, and after an aboriginal Native American presence.

From its inception, the Meadowcroft/Cross Creek Project was a multidisciplinary undertaking. Indeed, the overriding philosophy of the entire project necessitated a multidisciplinary perspective. Almost from the commencement of the project in 1973 and certainly by 1974, the central goal or theme of the operation was the systematic acquisition, analysis, and integration of any and all data bearing on the archaeology, history, paleoecology, geology, geomorphology, pedology, hydrology, climatology, and floral and faunal succession of the entire Cross Creek drainage. Moreover, this data gathering, analyses, and interpretation was to be executed with as great a degree of precision and employing the most sophisticated methodologies of which any of the project staff were cognizant. Additionally, and critically for the staff, this research was carried out virtually *without* temporal or fiscal constraints. In short, the project was designed to epitomize the so-called "state-of-the-art" data gathering and analytical methodologies and procedures.

As the foregoing suggests, the Meadowcroft/Cross Creek Project was essentially empirical in orientation and in some ways "old line" in philosophy. Meadowcroft Rockshelter and the Cross Creek drainage were never approached – whether in 1973 or the present – as vast laboratories in which to test explicit hypotheses or in which to seek logico-deductive covering laws or nomothetic truths about aboriginal behavior. Those who view archaeology as a vehicle or medium for the pursuit of such ends should not be denigrated for it, but theoretical considerations of this sort were not and a priori concern of the Meadowcroft project.

The implementation of the basic Meadowcroft/Cross Creek research strategy, simple though it was in theory, was, and remains, exceedingly complex in practice. Space precludes any detailed description of field methods, attendant analyses, or data management procedures, but these are available in Carlisle et al. (1982:16–30). Suffice to add because of the very extensive funding noted above, it has proven possible to implement the basic research strategy at a level of resolution rarely possible before and seldom encountered since.

Location and General Geology

Meadowcroft Rockshelter (36WH297) is a deeply stratified, multicomponent closed site (i.e., cave or rock-shelter) located 48 km southwest of Pittsburgh, Pennsylvania, and 4 km northwest of Avella in Washington County, Pennsylvania (Fig. 1). The site is situated on the north bank of Cross Creek, a small tributary of the Ohio River which lies some 12 km to the west. The exact location of the site is 40° 17′ 12″ North and 80° 29′ 0″ West (USGS Avella, Pennsylvania, 7.5′ Quadrangle).

Meadowcroft Rockshelter is oriented generally east-west with a southern exposure and stands some 15 m above Cross Creek and 260 m above sea level. The area protected by the extant overhang (i.e., the area within the modern dripline) is ca. 65 m^2, while the overhang, itself, is some 13 m above the modern surface of the site. When large roof blocks on the western (Old Roof Fall) and eastern (New Roof Fall) margins of the site were in place in the overhang, the habitable area was two to three times larger than at present. In addition to potable water potentially available from Cross Creek, springs are locally abundant in the immediate vicinity of the rock-shelter. The prevailing wind is west-east across the mouth of the shelter, which provides almost continuing ventilation and ready egress for smoke and insects. Finally, the "attractiveness" of the site is enhanced by the daily circuit of the sun, which warms the roof and walls of the rock-shelter and renders the local microenvironment more equable, especially during the colder months of fall and spring.

Geologically, Meadowcroft is located in what has been throughout the late Pleistocene an unglaciated portion of the Allegheny Plateau, west of the Valley and Ridge Province of the Appalachian Mountains and northwest of the Appalachian Basin. The surface rocks of this region are layered sedimentary rocks of Middle to Upper Pennsylvanian age (Casselman Formation), and the prominent lithologies are shale, quartz sandstone, limestone, and coal in

Meadowcroft: Geography and Culture, Fig. 1 General view of the Upper Ohio Valley and contiguous regions showing maximum southward extension of Wisconsinan glacial advance and the location of Meadowcroft Rockshelter

decreasing order of abundance. It is stressed that the nearest coal outcrop or seam is *not* expressed in or near the rock-shelter (Adovasio et al. 1992). Deformation of rock formations in the vicinity of Meadowcroft is very mild with a regional dip of 3–5° to the southwest.

Meadowcroft Rockshelter is formed beneath a cliff of Morgantown-Connellsville sandstone which is a thick fluvial or channel sandstone within the Casselman Formation of the Conemaugh Group of Pennsylvanian/Upper Carboniferous age. The cliff above the rock-shelter is 22 m thick, and the sandstone was deposited as two superimposed point bar or sand bar sequences within an ancient north-south flowing river. The rock within each point bar sequence changes from cross-bedded, coarse-grained sandstone to laminated fine-grained sandstone. The sandstone decreases in thickness along the Cross Creek valley both to the east and west with the maximum thickness evidenced at the rock-shelter.

The Morgan-Connellsville is technically an immature sandstone composed predominantly of quartz grains with minor amounts of mica, feldspar, and rock fragments. It is, taxonomically, subgraywacke to proto-quartzite in composition. A clay matrix is present between grains, and some zones within the cliff are cemented by calcium carbonate ($CaCo_3$). As discussed below, the mechanical breakdown or deterioration of the calcium carbonate bonds leads to grain-by-grain exfoliation or attrition of the roof and walls of the shelter and is one of the principal sources of material within the rock-shelter sediment pile.

The rock unit immediately underlying the Morgantown-Connellsville sandstone is the Birmingham Shale of the Conemaugh Group. This shale is a much-less resistant lithology, the erosion of which, via the downcutting of Cross Creek, produced the reentrant or rock-shelter which is Meadowcroft. The downcutting of Cross Creek began in the Sangamon Interglacial (ca. 125,000–75,000 BP) and continued through Early and Middle Wisconsinan times. Between ca. 31,000 and 21,000 RCYBP, a fine blue silty clay was deposited within the rock-shelter. This clay contains scattered sandstone blocks that spalled from the roof and walls of the shelter during downcutting and probably represents quiet water deposition from Cross Creek during early Middle Wisconsinan times. After Cross Creek resumed downcutting in the later Middle Wisconsinan, the rock-shelter was enlarged and never subjected to fluvial deposition again. After ca. 21,000 RCYBP, the rock-shelter would have been available for human occupancy/visitation had there been any populations in the area. The site, however, was not initially visited until considerably later. In any case, after ca. 21,000 RCYBP, the rock-shelter was "high and dry," far above even high water flood levels of Cross Creek.

Topographically, the region within which Meadowcroft Rockshelter is located is maturely dissected. More than 50% of the 14,164 ha Cross Creek watershed is in valley slope with upland and valley bottom in the minority. Maximum elevations in the Cross Creek drainage are generally above 396 m. At the divides on the east, elevations are above 426 m. Elevations at stream level are 310 m at Rea on the south fork of Cross Creek, 276 m at Avella, and 193 m normal pool level at the confluence with the Ohio River.

Within the Cross Creek watershed, the main stem of Cross Creek flows for some 37 km. The maximum north-south width of the watershed is ca. 15 km. The prevailing stream pattern is dendritic with numerous small creeks and runs supplying the main stem of Cross Creek. The steep gradient headwaters and tributaries of Cross Creek have their sources in the hills of central Washington County. Cross Creek and its three major tributaries (i.e., the north, middle, and south forks) have an average gradient of 0.4%. Most of the gradient is in the upper portions of the watershed where streams are small and of low volume. The drainage is northwestward to westward toward the West Virginia-Ohio border and the Ohio River.

Cross Creek exhibits a remarkably asymmetric drainage pattern with the northern tributaries significantly shorter than those on the south. Consequently, the drainage area to the south of Cross Creek is much larger than its counterpart to the north. This condition is probably the result of a

drainage pattern superimposed on the 3–5° regional dip noted above.

Because of the aforedescribed, dissected, and steep nature of the local terrain, the movement of human or animal populations from the Ohio River to the interior of Pennsylvania or in the opposite direction is, literally, funneled along drainages like Cross Creek. Suffice to note that any human populations moving along this natural artery who encountered Meadowcroft Rockshelter at the end of a long day of pedestrian and/or a combination of boat and foot travel would have potentially found the site to be an attractive, if temporary, habitat for a sojourn.

Stratigraphy and Dating

Sediment emplacement at Meadowcroft Rockshelter is the combined result of weathering and downslope (i.e., colluvial) movement of boulder-sized to clay-sized materials both from the directly contiguous upland surfaces and the Morgantown-Connellsville cliff.

Four distinct sources have supplied sediment to the Meadowcroft colluvial pile. As indicated above, a silty clay deposit just above the Birmingham shale probably represents quiet water deposition from Cross Creek during Middle Wisconsinan time when stream level was some 13 m (ca. 43 ft) above present levels. There is no recurrence of this sediment source later in the sequence underscoring the basic fact that *no* fluvial-emplaced fill accrued within the rock-shelter during the entire span of human occupation/visitation.

The second contributory sediment source is the release of rock fall from the Morgantown-Connellsville cliff. Sizes range from diminutive granules (<2 mm) up to very large boulders. Definite changes occurred in the amount of rock fall release through time with periods of stability punctuated by episodes of much more active rock release. Though the exact mechanism of rock fall detachment is not known, it appears that some combination of water movement, freeze/thaw, and, perhaps, root penetration along fractures in the sandstone are the critical processes.

The third sediment source is grain-by-grain attrition from the sandstone cliff. The sediments derived from this source consists of individual sand grains, predominantly quartz, with size ranges of 0.25–0.062 mm and small rock fragments with a size greater than 4 mm. This sediment source derives from the breakdown of calcium carbonate ($CaCo_3$) cement in the sandstone and provides a constant "rain" of sediment on the colluvial pile. The rate of attrition is clearly related to both precipitation and lower temperature, especially with extreme diurnal temperature change. During periods of increased rain and lower temperature with large daily fluctuations, the amount of sediment from this source increases. Attrition is the primary sediment source at the site, especially before the major roof spalling events.

The fourth sediment source at Meadowcroft Rockshelter consists of sheetwash from the contiguous uplands during rain storms. With the exception of the silty clay deposited at the base of the colluvial pile, sheetwash is the principal source of clay-sized materials at the site. Sheet wash becomes an important sediment source *only* after the major roof spalling episodes.

The relative importance of the major sediment sources clearly varies through time with one source, quiet water fluvial deposition, inoperative for the period of human/visitation use and the others differentially contributing throughout the occupational sequence.

The relative contributions of the three non-alluvial sediment sources are the principal factors via which the various Meadowcroft strata are distinguished. Within the site, there are 11 strata labeled with Roman numeral suffixes beginning with the earliest stratum (Stratum I) and proceeding to the latest Stratum XI. Stratum I is the culturally sterile basement of the site and is essentially synonymous with the Birmingham shale. The upper portions of this shale are heavily weathered and texturally friable, while the deeper portions become progressively indurated. The quiet water deposition of alluvial clay separates Stratum I from the remaining strata (II–XI).

The ten strata above Stratum I are individually variable in overall thickness, horizontal extent,

grain size(s), and geochemistry reflecting the differential operation of the various contributory sediment sources. All of these strata with the notable exceptions of VI and X are continuous across the site and many contain microstrata. The maximum thickness of the colluvial sediment pile at Meadowcroft Rockshelter is ca. 4+ m (13–15 ft).

The stratigraphic sequence at Meadowcroft Rockshelter is anchored by some 52 radiocarbon dates (Fig. 2) processed by four different laboratories. All but four dates are internally consistent and in absolute stratigraphic order, and those low-magnitude reversals occur in the Middle Archaic, Late Archaic, and Late Woodland periods. It should be stressed that not even the site's most persistent and strident critics have questioned the validity of the 39 dates that are younger than the assay of 12,800 ± 870 RCYBP. These samples include the "later" Paleoindian period as well as the entire Archaic, Woodland, Late Prehistoric, and Historic periods and are consistent with the ages of directly associated materials recovered from other sites. *Any* questions that have been posed, recently or in the past, have been directed solely at the remaining 13 dates, only 6 of which have undeniable and extensive artifact associations.

Suffice to note, most criticisms of the radiocarbon dates from Meadowcroft are focused on the lower culture-bearing strata or portions thereof (i.e., middle and lower Stratum IIa) and their attendant radiometric dates. Four decades of criticism revolving around these dates, especially those that are earlier than 11,500 RCYBP, have focused on the alleged particulate or non-particulate contamination of *only* the oldest samples. There is no evidence of any form of contamination of any of the older Meadowcroft Rockshelter samples, however, and there now appears to be an emerging consensus on the general antiquity of the site's deepest levels.

As noted by Adovasio and Pedler (2013:514), applying the most conservative interpretation of the available chronometric data, the most recent age for the presence of Paleoindian populations in this portion of the Ohio River basin is in the range of 12,000–10,600 RCYBP (13,870–12,660 cal BP). Radiometric dates on charcoal from a series of firepits identified in lower Stratum IIa range from 16,175 ± 975 RCYBP (20,476–18,110 cal BP) to 12,800 ± 870 RCYBP (16,565–14,085 cal BP). If the six deepest dates at Meadowcroft Rockshelter that are unequivocally associated with cultural material are averaged, then humans were definitely present at Meadowcroft between 14,555 and 13,955 RCYBP (17,500–16,750 cal BP). The oldest date from lower Stratum IIa, which was run on a carbonized, bilaterally cut fragment of bark-like material, is 19,600 ± 2400 RCYBP (26,212 cal BP). The configuration of the dated specimen is fully consistent with plaiting strips employed in later Meadowcroft basketry and *may* be a fragment of a basket wall. In any case, it is anthropogenically altered and suggests that the earliest Meadowcroft visitation may have occurred even earlier than 16,750 cal BP. It should be stressed, however, that this date and a second one (19,100 ± 810 RCYBP [21,000 cal BP]) on different material were both obtained from very small diluted samples, and both are non-AMS assays with obviously high standard deviations.

Summary of Cultural Features

Some 276 cultural features were identified at Meadowcroft Rockshelter. The most common features are firepits and charcoal lenses followed in decreasing order of abundance by extensive, accidentally or intentionally burned areas called fire floors; refuse/storage pits; concentrations of lithics, ceramics, and bone indicative of specialized activity areas; and roasting pits. Most of the firepits throughout the sequence are relatively simple constructions, unlined and unrimmed, and clearly represent single-use, short-term events (though some of the later Archaic and Woodland fire features are more elaborate). These later fire features sometimes reflect multiple-use episodes and are occasionally lined and rimmed. Collectively, the incidence of cultural features at Meadowcroft in conjunction with other proxies may constitute a coarse gauge of the intensity of site use through time, a topic addressed further below (see "Overview").

Meadowcroft: Geography and Culture, Fig. 2 Radiocarbon chronology from Meadowcroft Rockshelter (36WH297)

Artifacts

While the exact moment of the initial visitation/use of Meadowcroft Rockshelter remains problematic, the material culture suite of its first visitors and their immediate successors is far easier to characterize. The lithic artifact assemblage associated with the earliest Meadowcroft populations has been briefly described and illustrated in numerous publications (e.g., Adovasio et al. 1988; Adovasio and Pedler 2004; Fitzgibbons 1982) and was intensively analyzed by Boldurian (1985). Though somewhat compromised, or at least veiled, by the relatively small number of specimens (ca. 700), it is possible to characterize the lithic technology of the inhabitants of Meadowcroft Rockshelter and its contemporary sites/components (e.g., the Krajacic site and the Mungai Farm site complex) in the Cross Creek drainage.

The most common element in the early Meadowcroft Rockshelter lithic suite is debitage. As noted previously (e.g., Adovasio and Pedler 2004:147), the Meadowcroft lithic debitage sample clearly reflects secondary and tertiary core reduction from late-stage manufacture and especially the refurbishing of finished implements. The specimens of debitage strongly indicate that the earliest visitors to the rock-shelter brought with them an essentially curated lithic tool kit. Interestingly, the initial Meadowcroft visitors and their immediate descendants seemed to have exploited – or utilized through exchange – raw materials from a relatively far-flung series of quarries. These include Flint Ridge in Ohio, the Ondanga outcrops in New York, several Kanawha chert sources in West Virginia, the Pennsylvania Jasper quarries well to the east of Meadowcroft, and the local Monongahela chert outcrops in the Cross Creek drainage. This wide-ranging procurement pattern supports Custer's (1984) "serial quarry" exploitation scenario or, alternately, suggests that the regions earliest inhabitants were already part of a distant exchange network.

The flaked stone artifact suite from lower and middle Stratum IIa at Meadowcroft Rockshelter contains small prismatic blades or blade flakes (Fig. 3) that were detached from small, carefully prepared cores. Although complete cores were not recovered from Meadowcroft Rockshelter, the artifact assemblage from the nearby Krajacic site contains a great variety of the distinctive Meadowcroft-style blade or blade-flake implements and small, cylindrical polyhedral cores (Fig. 4). These cores and associated blade flakes (Fig. 5) were recovered from the Krajacic site after the initial study of the early Meadowcroft lithic assemblage was undertaken in 1975, and they precisely parallel the core reduction strategy posited for the Meadowcroft blades or blade flakes.

In 1976, a small lanceolate biface (subsequently named the Miller lanceolate after Albert Miller, the site's discoverer) was found in situ in the uppermost living floor of Stratum IIa at the site. This surface is bracketed by radiocarbon assays of 11,300 ± 700 RCYBP (13,350 cal BP) and 12,800 ± 870 RCYBP (15,250 cal BP), respectively. At the very least, this unfluted point is penecontemporaneous with the Clovis horizon, or, at most, it is as much as a millennium older (Fig. 6). As of this writing, the Miller point from Meadowcroft Rockshelter is the only specimen of its type recovered from a directly dated stratigraphic context. A second complete Miller was recovered from a surface context at the Mungai Farm site, and, as noted below, a probable fragmentary Miller was identified at the Krajacic site.

Because the Meadowcroft and Mungai Miller points were extensively resharpened in antiquity, it is extremely difficult to formulate even a provisional typological description. Adovasio et al. (1988) posited that the original Miller point(s) before resharpening were almost certainly longer, and further, that the angles of articulation between the lateral margins and the base suggested that the maximum width may have been achieved toward the distal or pointed end of the biface. One fragmentary artifact from the Krajacic site collection conforms almost exactly in most of its diagnostic attributes to the posited un-resharpened Miller "prototype" (Fig. 7). More recently, a complete, un-resharpened Miller point was collected from a surface context at the Mungai Farm site, confirming not only the proposed length of the posited prototype but also the preponderant width at its distal end (Fig. 8).

Meadowcroft: Geography and Culture, Fig. 3 Small prismatic blades from middle Stratum IIa at Meadowcroft Rockshelter (36WH297)

Taken in conjunction with the prismatic blades and prepared cores, these data very strongly suggest that the initial visitors to Meadowcroft Rockshelter brought with them a durable toolkit that was sophisticated, technologically standardized, and based on a small polyhedral core and blade technology of distinctly Eurasiatic flavor.

Despite the fact that conditions of preservation at Meadowcroft Rockshelter scarcely approximate the dry, closed sites of western North America, a few perishable artifacts were recovered from the site. These include artifacts of plant fiber, bone, and wood that are represented by simple plaited basketry, punch and awl fragments, and a bipoint, respectively. Not only do these rare items

Meadowcroft: Geography and Culture, Fig. 4 Cylindrical polyhedral cores from the Krajacic site (36WH351), located in the Cross Creek drainage

provide a glimpse of non-durable technology of the earliest Meadowcroft populations, because of the anthropologically and archaeologically documented association of perishable technology with women (Adovasio et al. 2007), these *items* may inform about *some* of the activities of that gender at the site.

The later Archaic and Woodland artifacts from Meadowcroft are again dominated by lithic items, though scattered perishable artifacts do occur. The lithic tool kits are dominated by curated forms, especially projectile points and other utilitarian bifaces, while the associated debitage continues to reflect an emphasis on refurbishment and resharpening. The non-durable artifact inventory again contains plaited basketry and a variety of awls and other forms.

Significantly, Meadowcroft Rockshelter has produced the earliest dated ceramic artifacts for the Upper Ohio Valley. Feature 60, a deep and reused fire pit with its origin in Stratum IV and base in Stratum III, yielded a half-moon cord-marked vessel with an associated date of 2815 ± 85 RCYBP (3065–2845 cal BP). A second half-moon vessel from deeper in the same feature has an associated date of 3065 ± 80 RCYBP (3358–3156 cal BP). This ceramic type is restricted at Meadowcroft Rockshelter to Strata III and IV and constitutes the basal ceramic type for not only the Cross Creek drainage but the entire Upper Ohio Valley as well.

Faunal Remains

At total ca. 956,000 specimens, Meadowcroft Rockshelter yielded one of the largest collections of faunal and floral materials ever recovered from a single locus in eastern North America. Of these, some 115,166 (12%) were individually examined, identified, and catalogued by the late J. Guilday (Guilday et al. 1980). This sample includes all of the elements recovered during screening (dry and wet) as well as a representative sample of specimens recovered from flotation. It has been determined that the 115,166 individually scrutinized elements represent no fewer than 151 vertebrate taxa and 149 discreet species. The species total includes 66 avian species (44.3% of all represented species), 44 mammalian species (29.5%), 26 reptilian species (17.4%), 8 piscine species (5.3%), and 5 amphibian species (3.7%) (Guilday et al. 1980). The most common species at Meadowcroft Rockshelter are listed in Table 1. A complete listing of the vertebrate faunal remains is provided by stratum and excavation level in Guilday et al. (1980: Table 4).

The vast majority of the site's identified vertebrate faunal remains (ca. 93% of the sample) derive from disintegrated, digestive pellets regurgitated by raptors, primarily owls, which formerly roosted on the cliff face of the rock-shelter during the accumulation of its deposits (Adovasio et al. 1984:357).

As Table 1 indicates, the three most common species at the site are southern flying squirrel (*Glaucomys volans*), passenger pigeon (*Ectopistes*

Meadowcroft: Geography and Culture, Table 1 Number of Identified Specimens (NISP) and minimum number of individuals (MNI) for taxa identified at Meadowcroft Rockshelter

			MNI	
Taxon	Common Name	NJSP	Total	% Site Total
Glau comys volans	southern flying squirrel	22,721	2,503	14.4
Ectopistes migratorius	passenger pigeon	7,050	810	9.2
Bufo sp.	toad	6,748	517	4.1
Peromyscus cf. *leucopus*	white-footed mouse	451	229	J.8
Tamias striatus	chipmunk	556	101	1.5
Blarina brevicauda	short-tailed shrew	264	88	1.5
Mele agris gallopavo	wild turkey	696	87	1.3
Mfrrotus pinetorum	woodland vole	154	75	1.0
Parascalops breweri	hairy-tailed mole	247	59	1.0
Bonasa umbellus	ruffed grouse	319	56	80.3
Total		39,206	4,525	80.3

SOURCE: Dirkmaat et al. (1993:Table 4)

migratorius), and toad (*Buffo* sp.) which collectively account for 68% of all recovered vertebrates. One of these species, flying squirrel, comprises 71% of all mammalian species, 94% of all squirrel species, and 44% of all identified vertebrate individuals recovered from Meadowcroft. The small size, nocturnal habits, conspicuous foraging strategy, and large population size of this rodent in mast forest settings such as that surrounding the rock-shelter made it the most common raptorial prey species in the Meadowcroft assemblage. Indeed, flying squirrel elements dominate the site's vertebrate faunal remains from the Archaic and Woodland strata to the extent that the relative number of other species (with the notable exceptions of passenger pigeon and toad) is so low as to register as only minor inter-stratal fluctuations.

Like the flying squirrel, the ubiquitousness of toad and passenger pigeon remains similarly reflects their large local population size and, hence, ready availability as raptor food. As discussed below, at least two of these species may have also figured in anthropogenic diets.

Although clearly dominated by microfaunal species introduced to the site principally by raptors, some 7% of the total identifiable faunal assemblage at Meadowcroft Rockshelter is attributable to feeding activities by the human occupants of the site. The dietary roles of these species are indicated by the presence of cut marks on specimens or by their excavated context within cultural features, activity areas, and living floors. Though not marked by any anthropogenic alterations, some of the flying squirrel and passenger pigeon remains *may* represent human collection and consumption – if the presence and use of mist nets and the subsequent processing of entrapped specimens without substantial disarticulation are presumed.

While there is no direct proof of the incorporation of flying squirrels or passenger pigeons in the human diet at Meadowcroft, there is positive evidence for the taking and processing of elk, deer, and turkey throughout the Archaic and Woodland periods.

Unfortunately, faunal preservation in the deepest and earliest levels at Meadowcroft Rockshelter is extremely poor. Only four vertebrate species, represented by diminutive fragments,

could be identified from stratigraphic contexts earlier than 11,300 RCYBP (ca. 13,100 cal BP). These include white-tailed deer, eastern chipmunk, southern flying squirrel, and passenger pigeon. Charred fragments of three other taxa are also present – toad, deer mouse, and colubrid snake – all of unknown specific ascription. While the possible dietary roles of deer mouse, chipmunk, flying squirrel, toads, and snakes are problematic, it may be assumed that white-tailed deer and, perhaps, passenger pigeons were "on the menu" of the earliest visitors at Meadowcroft. There are no extinct species represented.

From a paleoenvironmental perspective, it should be stressed that all the vertebrate faunal remains from later or upper Stratum IIa through Stratum XI suggest the presence of temperate Carolinian biota, typical of southwestern Pennsylvania, throughout the Holocene.

The scant vertebrate remains from the deeper or older levels of Stratum IIa likewise suggest but do not necessarily *demand* a temperate setting in the late Pleistocene. White-tailed deer, southern flinging squirrel, and passenger pigeon do, or did, range north rarely and marginally into Canadian zone situations and, also, have been recovered in dated late Pleistocene contexts with now extinct mammals. Their presence, albeit in very low numbers, in lower and middle Stratum IIa is, therefore, equivocal from a paleoenvironmental perspective.

Although not particularly common, mollusk remains are represented throughout the long Meadowcroft Rockshelter occupational sequence, though they are scarce in the very oldest deposits. All recovered mollusk specimens are locally present in the study area today, although several species have been extirpated from the segment of Cross Creek directly below the rock-shelter. A minimum of 35 terrestrial gastropod, 3 aquatic gastropods, and 11 naiad (freshwater mussel) species have been identified (Adovasio et al. 1984:358; Adovasio et al. 1985:88–100; Lord 1982:186–206).

The invertebrate faunal assemblage, like its vertebrate counterpart, indicates that the local microenvironment at Meadowcroft Rockshelter has been essentially stable for at least the past 11,300 years, before which time mollusks are poorly represented in the deposits. The extant data base also supports the presence of an essentially stable, humid, predominately oak-hickory woodland that was quite moist and shady but not particularly dense. Interestingly, despite the long-term pattern of stability, there are "moments" in the history of the site that appear to have been slightly drier and/or moister, cooler, and/or warmer. Of perhaps greater interest, while there is *no* evidence of the human consumption of terrestrial gastropods, there *are* clear indications of fresh water mussel collection, especially during the accumulation of Strata III through V, which subsume the Late Archaic, Transitional, and Early Woodland periods. Finally, there is a shift in terrestrial gastropod community composition which occurs with the appearance of early domesticates as the site (see "Floral Remains"). This change may signal some limited anthropogenic forest clearance to create more open garden plot areas.

Human Remains

Despite human visitation to Meadowcroft Rockshelter over literally thousands of years, human remains are very scarce at the site. In fact, there are no intentional burials of humans, and the few remains attributable to *Homo sapiens* are principally worn and discarded teeth (Sciulli 1982). Despite thousands of years of seasonal visits, it appears that either no one ever died during one of these generally very brief respites, or, if they did, their remains were transported elsewhere for interment. Of course, remains may have been interred in unexcavated portions of the site.

Several strata yielded non-dental human remains which, as noted previously, may have originated in burials elsewhere on the unexcavated portions of the site. Among these non-dental remains, potentially, the most informative derive from lower Stratum IIa. The specimens include the distal one-third of a middle hand phalanx with ca. one-half of the head missing. The specimen derives from an immature individual

and was directly associated with a date of 13,270 ± 340 RCYBP (16,711–15,532 cal BP). A second specimen from lower Stratum IIa is a highly weathered fragment of occipital bone from the lambdoidal suture area near asterion. This specimen was recovered in situ from a shallow firepit which produced a date of 13,240 ± 710 RCYBP (16,915–14,766 cal BP). Presently, these two human bones are among the oldest recovered from the New World. Unfortunately, these specimens are presently unavailable for additional research.

Floral Remains

Macrofloral remains comprise the most abundant class of ecofactual material recovered from Meadowcroft Rockshelter. Included in this ca. 1.4 million element collection is a fully processed, identified, and catalogued sample of ca. 30,000 items (2.14% of the total sample) ranging from moderately large sections of tree trunks and limbs (with and without bark), seeds, seed parts, fruits, and charcoal fragments to small quantities of pollen and spores. The remainder of this large floral assemblage was examined to ensure that the studied sample included adequate representation of all taxa and elements preserved on the site. The 30,000 identified specimens include all the plant remains extracted from 12 complete sediment columns excavated at the site. A fraction of the sediment from each stratum, microstratum, or excavated level within a stratum was processed via hydrogen peroxide (H_2O_2) flotation to deflocculate the sediment samples with minimal disturbance to the surfaces of charred floral elements.

Cushman (1981, 1982) summarized the floral inventory from Meadowcroft Rockshelter. Among the identified specimens of wood and charcoal as well as in the limited pollen sample are diversity of taxa within an attendant chronological range which, once again, present a picture of basic climatic stability, albeit, with intervals of low-level oscillations from ca. 11,300 RCYBP (13,100 cal BP) to the present. However, unlike the vertebrate and invertebrate faunal records from Meadowcroft Rockshelter, the macro- and microfloral assemblages suggest that temperate conditions extended into the late Pleistocene.

Two genera from the site's oldest plant-bearing sediments in lower and middle Stratum IIa are oak (*Quercus* sp.) and hickory (*Carya sp.*), which remain in evidence at the site to the present day. Similarly, pine (*Pinus* sp.) appears very early in the prehistoric record and persists to the present. Pine is particularly abundant from the latest Archaic until its decimation through logging in the very recent past.

Walnut (*Juglans* sp.), a very shade-tolerant species, persists from the initiation of human occupation to recent times in comparatively well-represented amounts. It is likely that walnut remained a dominant or co-dominant in the forest canopy during the entirety of its presence in the Meadowcroft area.

The only genera represented through time with greater frequency than walnut are oak and hemlock (*Tsuga* sp.), both of which are tolerant of a variety of light and moisture conditions. Oak is found in every time period at Meadowcroft and probably always was, as it is presently, a major component of the mixed conifer-hardwood forest in the immediate vicinity of the rock-shelter. The appearance of hemlock suggests the onset of possibly cooler/moister conditions, but the tolerance of this taxon for marginal conditions renders this interpretation conjectural.

Finally, hickory, elm (*Ulmus* sp.), ash (*Fraxinus* sp.), and beech (*Fagus* sp.) parallel each other in comparative representation through time. These species are all mesophytic and broadly tolerant of a variety of conditions. The greatest amount of beech recovered from Meadowcroft corresponds to the peak in hemlock, another moist habitat species.

Collectively, all the data presented above indicates fundamental environmental stability at Meadowcroft Rockshelter since well before the end of the Pleistocene. In this regard, it should be noted that although floral remains are scarce in the levels predating 11,300 RCYBP (13,100 cal BP), the mixed conifer-hardwood forest characteristic of later time periods may be extended back to the time of the site's earliest visitation(s).

Although this interpretation was initially challenged by the critics of the early Meadowcroft radiocarbon assays, it is now widely agreed that conditions to the south of the Wisconsin glacial front were far from uniform and that a mosaic of different environments existed well back into the Pleistocene.

Given Meadowcroft's unique physical and microenvironmental setting (cf. Adovasio et al. 1984: 365–366) as well as the fact that by the site's initial occupation, the ice front had retreated to nearly the present-day shoreline of Lake Erie, the late Pleistocene floral reconstruction advanced for the site is scarcely as anomalous as it once appeared.

In terms of diet, it appears that nuts, seeds, and fruits were subsistence elements of admittedly varying importance throughout the occupational sequence. Though walnut charcoal is absent, minor amounts of walnut and hickory nuts occur in the earliest occupational levels at the site. Walnut shells persist throughout the sequence, particularly in the more recent strata (VII–XI).

Fruits and seeds, other than nutshell, are also represented throughout the occupational sequence and notably include hackberry (*Celtis* sp.) in great abundance. While hackberry is absent from the Cross Creek drainage today (i.e., except as a lawn ornamental), prehistorically, it was apparently common and provided edible fruits with easily identifiable seeds from the late Pleistocene to recent times. While hackberry is also a dietary item for a variety of rodents and birds, its presence at Meadowcroft in storage, fire, and refuse pits is indicative of human emplacement and exploitation.

Cultigens from Meadowcroft Rockshelter include a small sample of maize (*Zea mays*) and squash (*Cucurbita* sp.) remains. Thirty-three specimens of corn (including 18 cobs) were recovered. The earliest corn specimens from the site (Stratum IV) is a small carbonized cob or what appears to be a 16-row popcorn with directly associated dates of 2325 ± 7 5 RCYBP (2222–2491 ca. BP) and 2290 ± 90 RCYBP (2183–2025 cal BP). The intermediate steps to longer and fewer rowed cobs are not directly evidenced at Meadowcroft, although most of the post-Stratum IV corn documents the local evolution of good-quality and high-yield maize varieties.

Cucurbit remains recovered from Meadowcroft Rockshelter include specimens from the top of Stratum III dated to 3065 ± 80 RCYBP (3358–3156 cal BP) and lower Stratum IV associated with dates of 2820 ± 75 RCYBP (3054–2856 cal BP) and 2815 ± 80 RCYBP (3057 2847 cal BP).

When the dates from the Meadowcroft cultigens were initially published, there was widespread skepticism about their accuracy and reliability; however, more recent research indicates the presence of squash in contiguous portions of the Northeast by ca. 5000 cal BP and corn by ca. 4000 cal BP.

As is addressed further below (see "Overview"), the introduction of nonlocal domesticates at Meadowcroft Rockshelter does not appear to have had major consequences either in the general trajectory of site use or the seasonality of visitation/occupation. However, as noted above, the introduction of cultigens *may* be synchronous with limited forest clearance near the site.

Overview

The basic interpretations of the timing and nature of the various sequent visitations/utilizations of Meadowcroft Rockshelter have not altered since 1982 (Carlisle and Adovasio 1982). Though still ongoing, the research at Meadowcroft since the initial excavations, attendant analyses, and publications in the 1970s and 1980s has only served to corroborate, expand, and occasionally modify earlier "conclusions" about the site. What has changed, indeed profoundly, since the original publication about Meadowcroft is the intellectual climate of the entire discourse about early humans in the New World, a topic beyond the scope of this contribution.

Chronology and Technology

The data presented above, as well as complimentary information published previously on the occupation of the Cross Creek drainage

(Adovasio et al. 1998), indicate that a much larger version of Meadowcroft Rockshelter and, by inference, a Cross Creek drainage not very dissimilar to today were initially visited or aboriginally occupied as early as 17,500–16,750 cal BP and, certainly, no later than 13,810–12,600 cal BP.

The flaked stone assemblage from the lower and middle portions of Stratum IIa at Meadowcroft as well as limited flaked stone materials from the Mungai Farm site complex, the lithic reduction station at the Krajacic site, and several other open localities in the Cross Creek drainage suggest that the earliest human populations who utilized the study area possessed a relatively sophisticated lithic technology. At a very early time, this technology included the production of diminutive blades or conical cores via indirect percussion as well as the manufacture of distinctive flake unifaces (or knives) and bifaces. Though dominated by utilized flakes, the earliest lithic industries in the drainage are by no means crude or technologically "backward" (see Adovasio et al. 1977: 87). Indeed, the reverse seems to be true.

Also included in the tool kits of the earliest Meadowcroft inhabitants are worked bone, modified wood, and basketry. Sties of this period are scarce, but it is clear that the entire length of the drainage was probably utilized (see "Spatial and Temporal Intensity of Rockshelter and Drainage Utilization," below). Further, it is apparent that in addition to a variety of exotic imported cherts, the earliest visitors to Cross Creek quickly began to exploit the local Monongahela chert resources.

Despite the ephemeral and obviously transitory nature of the earliest occupation of the drainage as it is reflected in lower Stratum IIa and the lower portion of middle Stratum IIa at Meadowcroft (as well as elsewhere, see below), it is clear that these early and presumable highly mobile groups of hunters and foragers represent the *chronological baseline* not only for the occupation of the Upper Ohio Valley but also for the lower reaches of the northeast and eastern North America.

Later Paleoindian utilization of both the Meadowcroft Rockshelter and the Cross Creek drainage is evidenced in the upper levels of middle Stratum IIa at Meadowcroft and at the Krajacic site and the Mungai Farm site complex. The occurrence of complete Clovis points from elsewhere in the drainage attests to the continuing use of the area in the so-called "classic" Paleoindian times. Despite the appearance of both Miller Lanceolate and Clovis points, the basic tool kit remained essentially unchanged. The perishable tool kit from the rock-shelter continued to include basketry, modified bone, and wood.

The latest Paleoindian occupation of the drainage is signaled by the recovery of a series of Plano-like points from the Mungai Farm site complex. Despite the absence of diagnostic materials, the presence of lithic debitage, ash, charcoal, incinerated bone, and limited plant material indicates that Meadowcroft continued to be used intermittently during this time. If the data from upper Stratum IIa at Meadowcroft is representative, the lithic tool kit continued to feature utilized flakes with limited numbers of bifaces, unifaces, modified bone, and wood. Basketry also persisted.

Occupation of both the rock-shelter and the Cross Creek drainage during the Early Archaic is evidenced by a series of diagnostic projectile points from a variety of open sites in the study area. Once again, it should be noted that Meadowcroft clearly was utilized during the Early Archaic despite the low number of flaked stone diagnostics. Two radiocarbon dates in the tenth and ninth millennia BP as well as extensive incinerated bone, limited lithic debitage, a variety of non-firepit cultural features, and abundant plant remains all indicate that the site was *not abandoned* at that time. Indeed, as noted by Adovasio et al. (1977: 88), the portions of the rock-shelter that have produced both terminal Paleoindian and Early Archaic materials are coextensive with the massive roof spalling event that separates Stratum IIA from Stratum IIb as well as a later series of less dramatic spalling episodes. It is strongly suggested that materials ascribable to the period ca. 10,950–8950 RCYBP are much more likely to be abundant east of the epicenter of the collapse rather than *in* or *on* the piles of spalls and roof blocks themselves. Again, if Meadowcroft is any reflection, Early Archaic tool kits included utilized flakes, limited numbers of bifaces and unifaces, as well as modified bone, wood, and

basketry. Significantly, the small blades with faceted and/or ground platforms so characteristic of the Paleoindian period at both the rock-shelter and elsewhere in the drainage disappear abruptly. The only "blades" recovered from any Archaic contexts are so dissimilar to the Paleoindian forms and so unstandardized as to suggest that most of them are "accidents." This is supported by the disappearance of conical cores as well.

The "beginning" of the early Middle Archaic utilization of Meadowcroft is marked by the appearance of Morrow Mountain-like and Kanawha Stemmed forms at the rock-shelter and the occurrence of Stanly and Kanawha points at both the Mungai Farm site complex and elsewhere in Cross Creek.

Utilization of Meadowcroft and the Cross Creek drainage throughout the duration of the Archaic is attested to by the recovery of a wide number of temporally diagnostic points. It is of some interest to note that there is greater typological diversity to the non-projectile point-flaked stone assemblages, at this time, both at Meadowcroft and at other Late Archaic or terminal Archaic sites. This is paralleled by increased diversity among all the perishable "assemblages" except basketry.

The onset of Early Woodland occupation at Meadowcroft and/or other localities in the drainage is marked by the persistence of several Late Archaic point types and by the appearance of Cresap Stemmed, Adena Ovate Base, and Robbins Stemmed point types. The Early Woodland at Meadowcroft is also evidenced by the early appearance of half-moon cord-marked ceramics and cultigens. The lithic and the perishable tool kits are more diversified typologically than previously, but the basically utilitarian character of the flaked stone assemblage persists as reflected in the high numbers of recovered utilized flakes. Diagnostic Middle Woodland points from Meadowcroft and from the study area in general indicate continued occupation during this period.

Late Woodland utilization of Meadowcroft is marked by various triangular points. In both the Middle and Late Woodland, the basic character of the non-projectile point flaked stone does not change appreciably. The Middle and Late Woodland levels at Meadowcroft, however, are somewhat depauperate in all classes of artifacts for reasons to be discussed below.

Spatial and Temporal Intensity of Rock-Shelter and Drainage Utilization

Many indices or proxies can be employed to gauge the spatial and temporal intensity of aboriginal utilization of Meadowcroft Rockshelter and the Cross Creek drainage. These include counts of sites/components per chronological period corrected for length of the period, numbers of temporally diagnostic artifacts per period (again corrected for length of period), as well as quantification (both with and without correction factors) of the artifactual and ecofactual data by stratigraphic level at Meadowcroft. Significantly, whatever measure or combination of measures is employed, it is clear that a slow but steady increase in the use of the drainage is evidenced from the onset of occupation in the Pleistocene through the end of the Middle Archaic. While there is apparently a dip or "regression" in the Middle Archaic, it is uncertain whether this is "real" or an artifact of sampling or identification.

Despite the fact that the entire drainage shows a scattered, almost ephemeral Paleoindian occupation generally at higher elevations (with the notable exception of Meadowcroft), and characterized by few if any real base camps, the Early Archaic materials are differentially distributed spatially with a concentration in the headwater areas of the drainage, particularly near the Mungai Farm site complex. Scant representation is found elsewhere at that time period, but the reasons for this are imperfectly understood at best.

The Late Archaic in the drainage, the period from ca. 5950–3050 RCYBP and especially the latter portion of that period, simultaneously witnessed a rise in numbers of sites and diagnostic projectile points as well as a dramatic increase in rock-shelter utilization; this underscores the appearance of genuine base camps. Extensive reduction of local lithic resources also characterizes this period with the appearance of flimsy "surface structures" at one of the two major lithic reduction localities, Cross Creek Village (36WH293). Additionally, the greatest range of

topographic settings was employed at this time for site placement. The magnitude of the change in intensity of drainage utilization during the Late Archaic and terminal Archaic (especially if the preceding Middle Archaic actually should prove to be poorly represented) is sufficiently striking that it suggests genuine population increase of a considerable magnitude.

Continued intensive utilization of the drainage is indicated during the Early Woodland, a time when Meadowcroft was still a base camp with other base camps located sporadically throughout the drainage. Thereafter, although there was a decline on rock-shelter utilization due to massive rock fall, the drainage continued to be heavily utilized in the Middle Woodland but, perhaps, in a different fashion than previously.

During the Late Archaic, a tendency developed to place sites on or near tributaries that provided access to adjacent drainages and which collectively are both much larger and ecologically richer than Cross Creek. This pattern intensified through the Early Woodland so that by the Middle Woodland, base camps for the aboriginal visitors to the Cross Creek drainage actually appear to be *outside* it in the "more attractive" contiguous drainages. A possible exception is the area near the Avella Mound (36WH415) which once may have had a Middle Woodland base camp of some size but which is now obliterated.

By the Late Woodland, base camps were absent from Cross Creek, and the number of known sites is low. Utilization of both the rock-shelter and the drainage persisted, however, and doubtlessly reflects an influx of hunting and foraging groups from permanent villages located outside the drainage.

It should be reiterated at this juncture that the horizontal or spatial distribution of occupational materials (and, hence, the loci of human utilization) at Meadowcroft Rockshelter has been determined by roof spalling events which dictate the amount of available dry, level floor space. The occupational record at the site consequently can deviate (as noted above) from that in the rest of the drainage due to site-specific geomorphic circumstances/constraints.

The general scarcity of late Paleoindian and Early Archaic materials at the site reflects very specifically the consequences of roof falls, while the apparent decrease in utilization of the rock-shelter after ca. 1665–1290 RCYBP likewise reflects the collapse of the huge New Roof Fall. Nonetheless, there are broad concurrences in the occupational history of Meadowcroft and in the adjacent Cross Creek drainage which can be taken to reflect the natural incidence and intensity of utilization of both settings.

Environment, Seasonality, Subsistence, and General Character of Site Utilization

Perhaps few subjects, exclusive of the lower and middle Stratum IIa radiocarbon dates, have engendered more discussion than the early environment of Cross Creek as interpreted at Meadowcroft Rockshelter. The absence of extinct Pleistocene big game animals and the presence of deciduous floral elements in very ancient levels have been extensively debated whenever the rock-shelter has been discussed.

In this regard, it can only be reiterated that all the extant ecofactual information, specifically including macrofloral, macrofloral, macrofaunal, and microfaunal remains as well as various categories of geological data suggest that from *at least* 11,250 or 10,950 RCYBP to the present, the environment of Cross Creek was essentially *modern* in aspect. This is not to suggest that there have been no changes over the past 11,000 years, as the data presented above indicate that cooler and/or moister as well as warmer and/or drier intervals *can* be detected in the environmental record. Specifically, the plant and invertebrate remains suggest some shift in forest species composition with indications of fluctuating temperatures before, during, and after the so-called Altithermal episode.

Conditions seem to have been considerably warmer and perhaps drier during the Middle Archaic and early Late Archaic (5950–3950 RCYBP) as well as immediately after the Middle Woodland. The magnitude of these changes is presently unknown, but, clearly, they should not be overstressed. Few if any readers have been concerned with or take exception to the

reconstruction of the latest Pleistocene or Holocene environmental history of the drainage. Rather, the focal point has been the lower and middle Stratum IIa deposits with their deciduous forest elements and lack of extinct Pleistocene fauna. As has been emphasized, these levels – especially outside the modern dripline – are very poor in terms of preservation; the material that is preserved is not large or numerous. What material is present, however, indicates both the presence within "striking distance" of the rock-shelter of both deciduous and coniferous trees with appropriate "modern" fauna. While this may seem unpalatable to some, it is not questioned by many others who realize the mosaic character of late Pleistocene environments in both the Midwest and Northeast. It is stressed, in this regard, that Cross Creek not only lies relatively far south of the Wisconsinan glacial front but occurs in a unique topographical setting which presently has many more frost-free days and generally higher mean annual temperatures than areas directly east or north of it. Specifically, modern weather records indicate that there are 40–50 more frost-free days in Cross Creek than on any of the higher elevations or contiguous drainages. Indeed, modern Cross Creek exhibits a temperate regime more appropriate to a more southerly setting than any other drainage in the area. If this is the case presently, it may well have been the case prehistorically. All the foregoing suggests that the environment which characterized the late Pleistocene in the portion of Cross Creek immediately adjacent to the rock-shelter was *not* radically different than at present.

The data recovered and analyzed from Meadowcroft to date argue that *throughout its history*, the site served as a temporary locus or station for hunting, collecting, and food-processing activities. The predominance of utilized flakes as well as projectile points which show multifunctional use coupled with limited numbers of bifaces and unifaces, the relative abundance of food bone, edible plant remains, and (at certain times) invertebrate resources plus perishable artifacts used in the acquisition, transport, or processing of these remains all support this conclusion. In marked contradistinction, the general absence of *extensive* evidence of the in situ manufacturing of lithic, ceramic, or shell artifacts militates against a "long-term or permanent occupation" interpretation of the site.

Significantly, while the intensity of site use changes through time – ranging from what may well represent very sporadic "day trips" in the Paleoindian, Early Archaic, and Middle Archaic periods to longer visits of perhaps several weeks or more in the Late Archaic through Early Woodland – the basic *function* of the site does not change appreciably even after the appearance of domesticated plants.

What is in evidence, however, are subtle changes in the apparent composition of groups using the rock-shelter. Despite the high incidence of projectile points and other flaked stone artifacts traditionally linked to hunting, the presence of basketry and the high incidence of modified bone (ethnohistorically associated with female activities) in the Late Archaic and Early Woodland levels at the site strongly suggest utilization by groups composed of both males and females at this time. Likewise, the relatively high incidence of Late Woodland ceramics and the low incidence of Late Woodland points imply a somewhat different pattern of collecting than is seen in the Paleoindian, Early Archaic, or Middle Archaic occupational horizons.

The primary subsistence modes of at least the various post-11,250 RCYBP Meadowcroft populations as directly reflected in the deposits include the hunting of deer and elk augmented by the taking of smaller game and perhaps bird egg collecting. The intensive collection of hackberries, nuts, and other fruits and seeds and the exploitation of riverine fauna, notably mussels, are also known from the archaeological record. While the data from the pre-11,250 RCYBP levels are (as noted above and elsewhere) rather limited, the extant information does at least suggest that the first visitors to the site also practiced a rather more diversified subsistence round than is normally associated with the Paleoindian period.

The hunting mode seems to have remained more-or-less constant throughout the post-middle Stratum IIa sequence, while the other subsistence modes mirror a number of potentially significant

changes. Hackberry exploitation sharply diminished in frequency after Stratum VII along with the collection of blackberry and blueberries. Conversely, the gathering of other nuts and seeds remained more-or-less constant. Similarly, exploitation of riverine resources, relatively insignificant before the Late Archaic, became markedly important immediately thereafter and remained so until the onset of Stratum VI (ca. 1665 RCYBP), when it virtually ceased. Doubtless, these changes reflect both climatically induced differential availability as well as specific food preferences. However, a full assessment of their significance is still underway. In recapitulation, the addition of cultigens toward the end of the long Meadowcroft sequence *does* appear to correlate with a diminution in the collection of certain wild plants although it does not seem to have changed the basic character of site use.

Examination of constituents of the dietary modes of the post-middle Stratum IIa Meadowcroft populations leads to the conclusion that the principal utilization of the site occurred during the fall of the year. While the hunting mode and, to a lesser extent, the riverine exploitation mode are seasonally independent, the nuts, berries, and seeds which constitute the "staples" of the collecting mode would have been most abundant in the fall, thus dictating the time of site occupation. If, as the floatation sample data suggest, egg collecting was pursued by some of the aboriginal visitors to the rock-shelter, then some limited spring utilization of the site is also indicated.

Data on the seasonality of the earlier occupations of the rock-shelter are so limited that they virtually preclude any cultural generalizations. However, if their apparently diversified subsistence strategy concentrated to any extent of plant resources, then the predominantly fall pattern of site utilization can be extended back into the late Pleistocene.

The data from all the other sites in the drainage except the Late Archaic seasonal camp of Cross Creek Village – which could not have been occupied in the spring because of flooding – are not conducive to reconstructing any seasonal patterns of aboriginal use. However, with the exception of a few localities, all of the open sites in the drainage appear to be short-term, limited activity loci presumable associated with one or another aspect of seasonally based hunting, collecting, and food processing.

Pending the ultimate completion of the data analyses from Meadowcroft Rockshelter and the 236 other sites in the Cross Creek drainage, it appears that it will be possible to link, at least, some of the aboriginal visitors to Meadowcroft with specific open sites and, hence, to "track" the movements of some aboriginal groups within the drainage. It is hoped that, by extrapolation, this will facilitate the generation of inferences on the seasonality of use of at least number of these open loci.

Media and Archaeology

Julie M. Schablitsky
Department of Anthropology, University of Maryland, College Park, MD, USA

Introduction and Definition

Whether an excavation stems from academic research or a legally mandated mitigation effort, the media has an insatiable appetite for archaeology. Indeed, human curiosity will always be piqued by stories about the mysterious past, and therefore archaeological discoveries will always be relevant. The propagation of human stories pieced together from artifacts, ruins/shipwrecks, and human remains lends itself perfectly to a foray of mediums that include printed formats (magazines and newspapers), radio, television (news programs and documentaries), and the Internet.

National and international media are interested in disseminating any archaeological search or discovery that may capture the interest of a larger audience; usually the stories are already familiar tales of the past, or the finds are significant enough to catch the attention of those unfamiliar with the history of the site. Although the topic of "archaeology and the media" can include various forms of electronic and published communication that influences mass audiences on anything related to archaeology, this entry will focus on the formats that archaeologists find most divisive and challenging to negotiate: published news media and television documentaries. While documentaries and local television news programs are made for television, they may be downloaded and viewed on portable electronic devices such as smartphones and laptops. Although daily newspapers and monthly magazines are distributed in print format, this time-sensitive form of media can also be accessed on the Internet where it can be lifted and posted in multiple web sites including listservs and blogs. The various locations and methods of sharing information today underscore the impact the mass media can have on a single archaeology site as well as the discipline in general.

Key Issues/Current Debates

The Debate

The job of documentarian and newspaper editor is to sell stories. Admittedly, humans are attracted to narratives involving a mystery, especially the ones with valuable antiquities and dead bodies. Those who publish archaeology articles and produce scientific documentaries recognize this interest, and naturally their stories include links to sex, drugs, human sacrifice, cannibalism, human remains, gold, taboo behavior, and anything religious. The media also recognize that their public is interested in popular people and events as well as archaeological excavations related to controversial projects and local history. Consequently, most archaeologists have experience sharing information on their work to news reporters. Since the data produced from archaeological excavations results in new information about our past, it is imperative that reporters accurately relay details about these discoveries. Failure to communicate the meaning behind material culture can result in erroneous information about the past that counteracts the archaeologists' efforts to contribute to, contradict, or confirm what was previously known about that particular event, place, and/or person(s). News reporters must become an expert on the subject they are covering at that moment. Their educational background and previous exposure to archaeology will significantly affect the quality and accuracy of their article. For example, science writers often cover science-based stories and are often successful at comprehending the value and meaning of an archaeological discovery. They possess the ability

to extract valuable information from an archaeologist to produce a comprehensive article with few, if any, misrepresentations or errors. Unfortunately, this quality of news coverage on archaeology is the exception rather than the rule.

Many archaeologists have experienced being misquoted and, perhaps worse, the significance of their discoveries overshadowed, often in favor of sensationalism. Although this unintentional or intentional misrepresentation of research can leave a site and the scholar relatively unscathed, occasionally there may be a significant impact to the project. Although many scientists face challenges with the media, Middle Eastern archaeologists are regularly pulled into the spotlight whenever one of their findings could be used to support or emasculate a group's political or religious agenda. An example is the alleged confirmation of Jesus of Nazareth and Mary Magdalene's tomb in Jerusalem by the *Discovery Channel*. After reviewing the evidence, or lack thereof, many of the biblical archaeologists remain skeptical that this ossuary could ever be substantiated as the tomb of Jesus (Gibson 2006: 118; Meyers 2006: 118). Despite the lack of scientific proof, the public is still left holding this mystery in their hands without a decision on the authenticity of the discovery.

As this example demonstrates, protesting the delivery of archaeology on television through avoidance may be futile and perhaps even a disservice to the discipline. Additionally, there are organizations that attempt to legitimize their treasure-seeking agenda by incorporating archaeological methods into their operations. Unfortunately, such organizations tout themselves as "commercial marine archaeologists," thereby creating confusion and reinforcing the erroneous message that archaeologists are treasure hunters in search of gold and objects of monetary value. Considering the impact treasure hunters have on the public may encourage some archaeologists to share their research on documentaries in an attempt to dilute bogus representations of archaeology.

On the other hand, significant repercussions can result from sharing new archaeological findings with the media. An example of an injustice to American archaeology research created by media coverage is the excavation of the Donner Party camp in California. This popular Western tale involved a wagon train becoming stranded in the mountains where some of the emigrants resorted to cannibalism to stay alive. When archaeologists publicly announced they found no human bone at one of the campsites, the news headlines insinuated the project archaeologists proved the Donner Party never cannibalized the dead (Dixon and Schablitsky 2011). In reality, the archaeologists simply did not recover human bone because they did not dig in the location of the bodies or the bone may have decomposed in the acidic soil. In the end, the news media ignored the newly discovered data on daily life in the camp and the reconstruction of a starvation diet in favor of dramatic and inaccurate headlines. This perpetuation of misinformation and insinuation of a "cannibalism debate" took an infamous historical event and created a controversy where there was none. When irresponsible and slapdash reporting on important events can twist and obscure the public's perception of the past, how can we, or should we, trust and share our findings with the media? Is there a reason we should even televise our research when the same network airs programs on treasure hunting our heritage? Herein lays the quandary and the debate.

Published Media

As discussed, sharing archaeological findings can be dangerous since a single interview can create a barrage of problems that did not previously exist. When a site is just discovered and exciting finds have not yet been publicly shared, reporters and even documentary producers can exhibit a voracious appetite for the "new" and "spectacular." Of course, media coverage is not limited to projects that involve significant finds; often stories are published on what the editor believes their audience will be interested in reading. Local archaeology stories, for example, often include cultural resource management (CRM) archaeology digs that can be attached to controversial construction projects.

Some scholars believe that in order to avoid any misrepresentation of scientific results, the safest response to the media is to simply not engage with them or rely on popular print to reveal one's preliminary findings and interpretations. Many of these scientists clutch tightly to the belief that trusting a non-archaeologist to share their results is not worth the risk of losing control of how their data is delivered to the masses. Unlike 20 years ago, a bad newspaper article does not end up lining a hamster cage. Instead, it lives on indefinitely in an electronic format posted on news sites, blogs, and commentaries. Furthermore, many academic scientists believe that sharing information on their findings within a popular medium prior to appearing in a peer-reviewed publication is popularization and regarded as irresponsible and an unethical delivery of scientific data (Gregory and Miller 1998: 108; Clack and Brittain 2007: 35). Instead, they believe that scholarly results should be restricted to academic publications and proceedings. The downside to this type of exclusivity is that it removes the public's ability to easily access archaeologically produced information about our past. This latter point is extremely important if the archaeological data is gathered with local, state, or federal government funding.

Of course, there are advantages to allowing an archaeological project to be publicly exposed in the mass media. In particular, large and complex archaeological projects take months, if not years to plan. The excavation of shipwrecks, large ruins, and multiyear projects requires a large and regular infusion of funding. Offering a high-profile archaeological site up as a sacrificial lamb to the media gods for the economic good of the project, however, should not be entered into lightly. Once preliminary data surfaces, the principal archaeologists should consider limiting regular and thorough coverage of their work by the media if the finds could be easily misinterpreted or are controversial in nature.

Some would also argue that coordination with the media is a necessary step when federal, state, and local agencies comply with Section 106 of the National Historic Preservation Act (Kuhn 2002: 206). Cultural resource management sections of agencies and private firms often find local news venues that facilitate their compliance with the law by reaching mass audiences, especially those populations who do not have the ability to access electronic information (e.g., email and Internet posts). When an archaeological excavation is finished, many community members may be interested in knowing what was found and learned from the dig. Indeed, a 30-second television announcement or a follow-up article in the newspaper is an efficient, inexpensive, and effective way to communicate what the archaeologists found and how the community's tax money was expended on the project. Recently, the Federal Emergency Management Agency agreed to fund the stabilization of a riverbank in a small town in southern Minnesota. The local news media effectively articulated the process of Section 106 of the National Historic Preservation Act (Lindberg 2011), allowing a 90-year-old citizen to recount that ". . . the archaeologists will conduct a second phase of work if the first phase results in information about the old ferry landing" (*pers. comm*. Carmel Miller 2011). Indeed, published media is extremely effective at notifying community members from various educational backgrounds and generations about what archaeologists are doing, what they find, and what new information they have learned about a site. The media can be a successful tool to share archaeological findings with those who pay for the science.

The Documentary

The creation of archaeology programs has been a favorite topic of television documentary filmmakers for over 50 years. One of the first televised excavations covered the work of paleoanthropologists Louis and Mary Leakey (*National Geographic*, Dr. Leakey and the Dawn of Man, 1966). Today, television documentaries primarily follow two formulas; however, these formats may overlap one another. The most common documentary captures a recent discovery, often incorporating the project archaeologists, and if possible, additional data not yet released. Exploring an already discovered shipwreck and new

excavations on popular sites also makes popular television documentaries.

Another common format uses a professional host who visits well-known archaeological sites in places such as the Near East, Mexico, and South America. These host-led shows are quite successful and include programs such as "The Naked Archaeologist," "Digging for the Truth," and "Solving History with Olly Steads." As a result of the reality television movement, history-related documentary series are personality driven, and a strong host is crucial for the show's success. An attractive persona, enthusiasm for solving a mystery, and the ability to naturally communicate on camera are what is necessary to lead these types of documentaries and not a degree in archaeology. In other words, the success of the program is dependent on the personality, rather than the subject matter.

In an attempt to emanate scientific credibility and meet funding requirements yet secure high viewer ratings, networks may pair a team of graduate-degreed archaeologists with a professional host. Over 20 years ago, Tim Taylor created a science reality program that allowed the television audience to peer over the shoulders of archaeologists as they recovered Roman pottery sherds and exposed stone walls in neighborhood backyards and local farm fields in the United Kingdom. The program brought three professional archaeologists together but used Tony Robinson, known for his role as Baldrick in the popular BBC television show *Blackadder*, to host the show. Tony is shown becoming extremely animated as he peers into the trenches to find out what the archaeologists have just discovered and then turns to the viewing audience to deliver the news. He is the audiences' interpreter and asks the questions likely on the minds of the audience. The show is energized by his enthusiasm, and a sense of urgency hangs over the team since they only have 3 days to answer their questions. Remote sensing techniques such as ground-penetrating radar and magnetometry, referred to as "geophys," lead the archaeologists to subsurface anomalies that could be buried walls or other culturally created features. Mechanical diggers quickly strip off the modern overburden, creating long trenches that allow the archaeologists to quickly find what they were searching for in that area. The sites are amazing and include Roman ruins, human burials, and even a World War II aircraft. The present and the past converge in the program when food and craft demonstrations are participated in by one of the archaeologists – what does a medieval feast smell and taste like? How do you fight with an ancient weapon? The Time Team format is a unique concept since it uses professional archaeologists who are uncovering their finds as the camera rolls, rather than after the discovery. Indeed, the program's formula can easily be transferred to any place in the world that holds undiscovered secrets and an enthusiastic team of archaeologists.

Fifteen years after Time Team aired in the United Kingdom, PBS determined the American audience was ready for their own science reality television show. Although much less popular than the British version, Time Team America went into production in 2008 and aired five episodes on PBS over a year later. The British Time Team program sent one of their directors to script the show and direct the camera crews on historic and prehistoric archaeology sites across the United States. The show included an amateur host and artist, a team of five professional archaeologists, and a pair of geophysicists. Instead of discovering and digging new archaeology sites like the original Time Team, the filming took place on already known and established excavation sites located on protected lands and managed by public or university archaeologists. Although the sites held mysteries such as the Lost Colony of Roanoke and a hero tale about an enslaved African American establishing a town in the heart of the Midwest, the series did not initially get funded for a second season. PBS did not believe that the discussion on dark soil post molds, finding 150-year-old ceramic sherds, and picking up broken Clovis bifaces were visually exciting enough to keep American audiences' attention. In addition, there seemed to be too many archaeology personalities on camera. Despite these concerns, PBS found the show format promising and was encouraged by the original British version's success. After a 4-year hiatus, PBS secured a National Science

Foundation grant, and Time Team America went into a second season of production in the summer of 2012 with a professional host and a smaller team of scientists.

Pitfalls and Advantages of Archaeology on Television

Although there are many successful documentaries that accurately and effectively communicate scientific discoveries to the public, the dissemination of information to the masses using television still has its critics and for good reasons. All television documentaries are born from a question. Is there evidence of cannibalism at the Donner Party site in California? Was King Tut murdered? Did archaeologists find Jesus' tomb? If the director can attempt to answer such questions by interviewing scientists, examining objects, and in some cases, performing experimentations on camera, then the topic has a potential for a documentary. Before the camera rolls, the vision of the executive director on how to navigate through the story has already failed in the eyes of many archaeologists. Admittedly, the audience will never be provided the credentials of the scientists and/or hosts of the show, the months and years of logistical planning and research will not be addressed, and even the reasons the archaeologists found their discovery significant may be glossed over in favor of a sensationalized aspect of the story. The networks' goal is not to share wonderful archaeology discoveries and teach the masses about the importance of archaeology. Instead, they entered the world of documentary filmmaking to tell a story that explores a mystery that most people will find interesting enough to learn about; archaeology just happens to be one of those topics people find fascinating, along with sharks, the Bible, and military history.

Archaeologists who oppose working with production companies are concerned with blurring the line between the legitimate scientist and the amateur as well as producing an archaeology-themed documentary solely for the sake of entertainment. It is the rare archaeologist who does not take offense at documentaries that focus on "chasing mummies," legitimizing treasure hunting, or producing a program on a controversial subject with little scientific data to support any hypothesis. The big networks, such as *History* and *Discovery*, fail to differentiate between a scientific and financial endeavor – unfortunately, so does the viewing audience. Hollywood reinforces the treasure hunting = archaeology stereotype through movies such as the Indiana Jones series and Tomb Raider – it is a symbiotic relationship. In the end, the discipline's goal to produce solid data about the past by using material culture and patterns is thwarted by the message that archaeologists only care about finding artifacts and, perhaps worse, context is nothing.

Archaeologists who want to create, or agree to participate in, a documentary about their site often do so realizing the benefit in it for them. Setting self-promotion aside, many scientists do see the economic advantage in exposing their site. If asked, networks may be willing to donate several thousand dollars to the project in exchange for permission to produce a documentary on one's research. This influx of funding may allow the principal investigator to complete necessary analyses or to hire a temporary research assistant. In particular, high-profile sites may greatly benefit from an exclusivity contract with the network that allows them to document the site and release information in popular mediums for thousands of dollars. In these longer and more extensive documentary productions, archaeologists benefit from a relationship with the director who is more likely to address the archaeologist's concerns. In still other instances, the high public profile of a site created by mass media coverage can encourage future support in the form of partnerships and additional funding.

Future Directions

Admittedly, media coverage can be detrimental to the field of archaeology as slapdash reporting confuses details, sensationalizes findings, and legitimizes individuals and groups who financially profit from archaeology. Once the scientific field understands and accepts that the media is not

capable of always recognizing the true significance of a discovery, archaeologists may be able to work toward identifying the part of their research that is newsworthy without losing control of the data. It is possible for scholars to use the media to teach the public *who* archaeologists are and *how* they learn about the past using broken things and patterns in the soil. All archaeologists should understand how to negotiate with the media but also simultaneously recognize when the director or reporter could deliver a dramatically construed story rather than a report steeped in scientific realities (Frank 2003: 453; Holtorf 2007: 105). Documentaries want to make their production believable and they try to get there by being as truthful as possible, but the truth is not always captured in documentaries or science reality television (Hampe 2007: 123–5). In fact, as reality television evolves, the public may be increasingly misled and fed misinformation on discoveries for the sake of entertainment. If archaeologists choose to work with the media to deliver a message, they need to exercise caution, anticipate specific questions, and prepare sound bites that the public can digest. Simplifying the message (rather than dumbing it down), although difficult for many, is imperative to reach audiences, as well as reporters, unfamiliar with scientific rigor and theory.

Archaeologists are truth seekers. Their ultimate goal is to literally get to the bottom of a story using all methods and sources available to them. In simple terms, after they gather the data, it is organized, analyzed, interpreted, and compared against other scholar's research. The end result is publication of the interpretations and findings in peer-reviewed publications and/or technical reports. Somewhere in the middle of this scientific process, an opportunity for the media to document and report on the discoveries from a historical site may become available to the archaeologist. A documentary film cannot, and a director would not choose to, capture a comprehensive production that communicates the methods and theories used to reach conclusions about the subject at hand. The mass media is limited and is not the place to launch new data or, in some cases, controversial or sensitive findings without it first appearing in scholarly publications. In the unfortunate event that misrepresentations occur in the media, peers and the public could always be directed to published articles and books for clarification.

In sum, the public's interest in human history will not wane with the passage of time and neither will the media's desire to write about and produce documentaries on archaeology. Perhaps the only thing to change will be the format that archaeological discoveries are disseminated to the masses. It is hoped that archaeologists can appreciate the limitations of the mass media but still find a way to successfully navigate within those boundaries to responsibly share their discoveries with the public.

Medieval Archaeology

Sally M. Foster[1] and Sarah J. Semple[2]
[1]Department of Archaeology, School of Geosciences, University of Aberdeen, Aberdeen, UK
[2]Department of Archaeology, Durham University, Durham, UK

Brief Definition of the Topic

Medieval Archaeology is the annual journal of the Society for Medieval Archaeology, first appearing in 1957. It publishes original submissions of international significance, or national significance and of international interest, which further the study of the period from the fifth to the sixteenth century CE. While it maintains a special concern for the medieval archaeology of Britain and Ireland, it also provides a forum for the discussion of important finds and developments within this period from anywhere in the world, serving as a medium for coordinating the work of archaeologists and that of historians and scholars in any other discipline relevant to this field. The editorial committee strives to present the highest-quality research, work that not only reflects the breadth of the interdisciplinary period and geographical interests but also inspires and challenges in some way. Its international advisory board supports the editor in the delivery of an internationally respected, peer-reviewed journal.

As part of its 50-year celebrations in 2007, the Society made volumes 1–50 available free online (ADS n.d.), while through Ingenta/Maney Publishing volumes 44 onward are available electronically to its individual and institutional subscribers. In 2015 the journal was acquired from Maney Publishing by the Routledge Taylor and Francis group, and in 2016 the journal moved to two issues per year. All volumes from 1 to 62 are now available via Taylor and Francis online.

The contents (all color since 2011) comprise articles (with translated abstracts since 2007), notes, Medieval Britain and Ireland, and a substantial review section of primarily Europe-focused books. News now appears in the Society's biannual newsletter. Since 2007, the Society awards the Martyn Jope Award for the best novel interpretation, application of analytical method, or presentation of new findings. The Medieval Britain and Ireland section comprises a report and analysis of new finds from the Portable Antiquities Scheme and a section on highlighted projects or discoveries, accompanied by an index to all the medieval fieldwork for the year in question (since 2008 the Archaeology Data Service (ADS n.d.) makes the details of these archaeological projects available online).

Gerrard (2009) and Wilson (2009) discuss the evolving role and significance of the journal in the context of the development of the Society and attitudes toward the study of medieval archaeology. The Society and its journal have been instrumental and highly influential in this respect, the journal acting as the model for later European journals as the subject has expanded and matured. A constant for *Medieval Archaeology* is still the focus on international, multiband interdisciplinary perspectives, as well as substantive reviews. In 2017 to mark the 60-year celebrations of the Society, a retrospective virtual Anniversary Collection was published, with the free release of 20 past articles that represent the journals strength in interdisciplinary scholarship and its role in bringing new findings to press.

To date, the honorary editors have been Donald B. Harden (1957–1973), Richard Gem (1974–1978), D. A. Hinton (1979–1989), H. C. Mytum (1990–1997), John Hines (1998–2006), Sally M. Foster (2007–2012), Oliver Creighton (2013–2016), and Sarah Semple (2016–2018).

There is a separate Review and Medieval Britain and Ireland editor (Neil Christie since 2007).

Since 2009, *Medieval Archaeology* also has a deputy editor (Aleksandra McClain 2016–2018);

at times in the past, there was also an assistant editor.

Information on the journal and its contents can be found on the Society of Medieval Archaeology website https://www.medievalarchaeology.co.uk/ and via http://www.tandfonline.com/loi/ymed20.

Medieval Pottery Research Group (MPRG)

Duncan H. Brown
Medieval Pottery Research Group, c/o Museum of London Archaeology, London, UK

Basic Information

The MPRG was founded in 1975. At a time when medieval archaeology was still emerging as a credible discipline, it became clear that pottery studies needed consistency of direction and approach. Since then, membership has grown to around 300 and includes people from the USA, Japan, and all over Europe, as well as many institutions. The group is run by a council that includes the president, vice-president, secretary, treasurer, and editors, as well as three overseas representatives.

Major Impact

The purpose of the group remains the communication of knowledge and understanding, the provision of expertise through a network of regional groups, the development of training and educational activities to a variety of audiences, and advocacy of our interests to regional and national bodies.

The first of those aims is achieved through the publication of the annual journal *Medieval Ceramics* which has now reached number 32. A twice-yearly newsletter provides a less formal means of communication, while the occasional paper series includes more subject-specific titles and was launched with the comprehensive *Guide to the Classification of Medieval Ceramic Forms* (1998). The group also holds an annual conference, based each time at a different location, usually within the UK but also including trips to Holland, Germany, and Italy.

The regional group network covers England, Wales, and Scotland. Group meetings are organized at local venues and are usually an opportunity to view newly discovered pottery assemblages and share views and current interpretations. Some groups have also held training events aimed at local amateur societies, and an overall aim is to develop those into a more organized program. Training has also been offered nationally, with funding support from English Heritage, in the form of 2-day workshops in a variety of subjects including characterizing pottery fabrics, European pottery imported into Britain, Staffordshire pottery, and manufacturing techniques.

The MPRG has recently published a *Research Framework for Ceramic Studies in Britain* (Irving 2011), which comprises a survey of current knowledge and the state of the discipline, together with recommendations for the direction of future

research. This will also be vital to future advocacy in funding applications and regional and national research programs. One key challenge is to encourage younger researchers to join and participate, as there has been a noticeable decline in the teaching of post-Roman material culture in academic institutions. The John Hurst Travel Fund, set up to honor one of the group's founding fathers, makes a small annual grant available to young researchers needing assistance with travel costs for studies abroad, and previous recipients have been helped with visits to Jordan and the Faroe Islands.

Information on all this and more can be found on the group's website at http://www.medievalpottery.org.uk/. New members are always welcome.

Medieval Russia (Rus'), Archaeology of

Mark Brisbane
Department of Archaeology and Anthropology, Bournemouth University, Dorset, UK

Introduction

The Slavic colonization of Northwest Russia occurred in two waves coming from the territory of the western Slavs. The first, identified with the tribe known as the Krivichi and distinguished by their use of long barrows, took place in the sixth to seventh centuries. The second wave, identified with the Sloveni and their use of *sopki* (high, conical burial mounds), took place in the eighth to ninth centuries (Yanin 2007: 205).

Medieval Russia from the ninth to twelfth century is often referred to by the term Rus'. The origin of this name, and the populations and lands to which it refers, has been the subject of much debate that has affected both archaeologists and historians over many years. It is usually associated with Scandinavian settlers and tribal leaders, as the early chronicles describe Swedish Vikings coming from the Baltic area to settle and rule over a disparate group of Slavic tribes around the emerging town of Novgorod and its territory, which included the important hill fort known as Ryurik Gorodishche that controlled the waterways on the northern edge of Lake Ilmen. According to one possible theory, the name Rus', like the Finnish name for Sweden (*Ruotsi*),

might be derived from an Old Norse term for "the men who row" as rowing was the main method of navigating the rivers of Eastern Europe. The name Rus' would then have the same origin as the Finnish and Estonian names for Sweden, namely, *Ruotsi* and *Rootsi*, respectively.

Scandinavians are sometimes referred to in medieval Russian chronicles as Varangians, another name accepted as meaning Vikings with a Swedish origin. According to the *Primary Russian Chronicle* compiled in Kiev around CE 1113, the Rus' had relocated from the Baltic area to northeastern Russia, creating an early polity under the leadership of Ryurik. The descendants of Ryurik were the ruling dynasty of Rus' centered on Novgorod (from 862) and Kiev and the successor principalities of Chernigov, Vladimir-Suzdal, Galicia-Volhynia (after 1199), and eventually Moscow (which did not become a significant urban settlement and power base until the fourteenth century). Their dynasty is referred to as the Riurikid.

Historical Background

Primary Historical Sources

According to the earliest East Slavic record, known as the *Primary Russian Chronicle*, the Varangians were first expelled and then invited to rule over the feuding Slavic and Finno-Ugric tribes around Novgorod.

The part of the Chronicle that refers to this states that:

> The four tribes who had been forced to pay tribute to the Varangians (the Chuds, Slavs, Merians, and Krivichs) drove the Varangians back beyond the sea, refused to pay them further tribute, and set out to govern themselves. But there was no law amongst them, and tribe rose against tribe. Discord thus ensued among them, and they began to war one with another. They said to themselves, 'Let us seek a prince who may rule over us, and judge us according to custom.' Thus they went overseas to the Varangians, to the Rus'. These particular Varangians were known as Rus', just as some are called Swedes, and others Normans and Angles, and still others Gutes, for they were thus named. The Chuds, the Slavs, the Krivichs and the Veps then said to the Rus', 'Our land is great and rich, but there is no order in it. Come reign as princes, rule over us.' Three brothers, with their kinfolk, were selected. They brought with them all the Rus' and migrated (the *Primary Russian Chronicle* entry for either CE 859 or 862 depending on which version of the chronicle is used).

Development of the Subject

In the nineteenth century, the study of Russian medieval archaeology began with a period of antiquarianism, but by the late nineteenth century, the subject had become inextricably linked to nationalistic approaches that were becoming widespread across Europe. After World War I and the Bolshevik Revolution, this approach combined with a growing preoccupation with the ethnic origins of early medieval peoples, their settlements, and burial rites. Examples of this include the early fieldwork at Staraya Ladoga, where investigations, particularly of burial mounds, searched for evidence of Viking incomers to either support accounts from the chronicles or to demonstrate a Slavic national/ethnic tradition (often referred to as "the Normanist controversy") as views polarized about the extent and influence of Scandinavian migrants into Kievan Rus' in the ninth and tenth centuries. Under Stalin, nationalism was also used to legitimize political regimes using ethno-genetic studies.

The domination of ethnic origins and the role of typologies in supporting or countering various arguments about Vikings, Slavs, and indigenous tribes continued throughout much of the twentieth century. During the Soviet postwar period, this approach took on new significance, as it was seen as a relatively safe area of archaeological and historical research, whereas new approaches and the discussion of western ideas could place individuals into a position of conflict with the state with sometimes dire consequences. As recently as the 1980s, leading Soviet archaeologists found themselves in difficulties with the authorities due to their questioning of accepted Soviet interpretations of history. For instance, theoretical archaeologist Leo Klejn faced charges and a prison sentence partly for his questioning of the prevailing view of the Normanist question and for contradicting the orthodox Marxist theory of historical materialism. He was also persecuted for showing interest in Western ideas, such as the

New Archaeology, for publishing extensively in Western journals, and for having too many international contacts (Klejn 1991).

In the period of *perestroika* and the post-Soviet era (i.e., after 1991), Russian medieval archaeologists were able to contribute to academic debate within a wider, more open international forum. However, the economic crisis of the mid-1990s brought about its own problems of diminished resources in university departments and academic institutes, many of which had high numbers of staff but little money with which to pay them (Chernykh 1995).

Throughout all these twentieth-century upheavals, the Soviet and subsequently the Russian Academy of Sciences have supported archaeology in general and medieval archaeology in particular through the funding of fieldwork, research staff, and laboratories. The Institute of Archaeology in Moscow and the Institute for the History of Material Culture in St. Petersburg are the two main organizations for field archaeology throughout all of Russia. Both institutes have long pedigrees in high-quality archaeological work (the latter organization being established by Lenin himself). At the present time (2017), both institutes are run by medieval archaeologists (N.A. Makarov in Moscow and V.A. Lapshin in St. Petersburg).

University departments also play an important role in both national and regional archaeological research projects. For instance, the long-standing program of systematic excavations in Novgorod has been directed by the Department of Archaeology of Moscow State (Lomonosov) University every year since they were first begun by Professor Artemiy Artsikhovsky in 1932 with the exception of the war years in the 1940s. This connection has continued throughout the postwar and post-Soviet periods, first under the direction of Boris A. Kolchin, followed by Valentin L. Yanin and Alexander S. Khoroshev.

Key Issues/Current Debates

Key Sites

In keeping with the debate about the role and significance of Viking traders and settlers, the site of Staraya Ladoga, investigated since 1972 under the direction of A.N. Kirpichnikov, has been the subject of much interest to scholars of early medieval Europe. It was an important trading center (emporium) of the type well known throughout the Baltic and North Sea at this time, similar to Birka, Hedeby, and Ribe. According to dendrochronological evidence, the settlement of Ladoga emerged no later than CE 753 and quickly became an important trading place on the routes from the Baltic Sea along the River Volkhov, then via the Dnieper or Volga to the south or east. The generally well-preserved remains of timber buildings cover approximately 18 ha and represent continuous habitation from the mid-eighth century onward. It was a center for craft, administration, trade, and transportation, where Slavic, Finnish, Scandinavian, and other ethnic groups lived and traded. Much of the Arabic silver coinage that reached the shores of the Baltic Sea probably passed through it (Kirpichnikov 2004: 183).

Another site related to the question of Viking penetration into early medieval Russia is Gnezdovo, near Smolensk. This site has also been the subject of extensive investigation, producing a large range of artifacts, mostly from burials, that indicate extensive Viking connections. This has led archaeologists to address the formidable question of how extensive was the role of Scandinavians in the origins and development of the Kievan State. For an overview of Norse settlements in Eastern Europe between the eighth and tenth centuries, see Duczko 2004.

An important aspect of medieval archaeology in Russia has been the excavation of urban sites, the primary ones being Novgorod, Pskov, Suzdal, Vladimir, Rostov, and more recently Moscow. These investigations have had a tradition of focusing on the material culture, notably jewelry and other metalwork, and also on technological questions to do with the manufacture of iron and copper alloy objects. Another area of intensive study has been the organic remains of objects of wood and leather, particularly as many of the more extensively occupied towns, such as

Novgorod, have very deep anaerobic deposits where artifact preservation is exceptionally good. It was in this context that the first birch-bark documents were discovered at the Nerevsky excavations in Novgorod in 1951. Dating from the eleventh to fifteenth centuries, these documents now number over 1,000 from Novgorod alone, but with further examples found at other towns including Stara Russa, Pskov, Smolensk, Torzhok, Tver, Moscow, and Ryazan in Russia, Zvenigorod in Ukraine, and Vitebsk and Mstislavl in Belarus. These precious remains of largely domestic, sometimes mercantile, writing have been avidly studied by linguists and historians, as well as archaeologists, the leading experts being the historian V.L Yanin and the linguist A.A. Zalizniak.

Another aspect of medieval urban archaeology that has been much studied is town morphology: notably the layout of streets, properties, and open spaces. A great deal has been made of the so-called Republic of Novgorod dating from the twelfth to the fifteenth century where the *boyars* had a voice to equal, and occasionally veto, that of the Prince. They also elected their own mayor (*posadnik*). As a topographic feature, the outdoor space provided for the town *veche* (a popular assembly similar to the Norse *Thing*) should be recognizable archaeologically, and various ideas about its location have been put forward. In this way, medieval archaeology has been instrumental in the debate about notions of the state and statehood, as well as the organization of "democratic" or "republican" city life.

Recognizing and documenting the evidence for the Mongol invasions of the thirteenth century and their impact on urban places, such as Suzdal and Vladimir, is another recent theme, as is the investigation of the rise of Moscow in the fourteenth and fifteenth centuries. For example, recent work on rescue sites in Moscow, including the town's late medieval mint, has been carried out and recently published by the Institute of Archaeology (Krenke 2009).

It is worth noting that the Soviet era brought in some far-reaching and, for their day, innovative heritage protection laws in the 1960s. The most significant of these for medieval archaeology was "the protection of the cultural layer" first brought into effect in Novgorod and which ensured that archaeological deposits were either protected or excavated by approved archaeologists from the Academy of Sciences. However, changes to heritage protection in recent years have led to a more western approach to rescue archaeology as the involvement of private developers has brought about a more commercial approach to both urban and rural development. This has reduced the amount of research investigation but has increased the number of smaller investigations and extensive field surveys.

One of the positive outcomes of recent changes has been the emergence of landscape studies looking at rural settlement patterns through time, settlement shift, nucleation, and dispersal. A notable example of this approach has been the work of Nikolai Makarov, whose work in the Byeloozero region has been examining the evidence for the colonization of the northern region of medieval Russia as the principalities of Novgorod and Rostov-Suzdal vied for control of the rich fur-gathering lands that lay between Lake Byeloe and the White Sea. In particular, this survey work has been investigating the formation of a loose but stable settlement pattern in the eleventh to thirteenth centuries, which covered a vast area populated by Finno-Ugric groups who paid tribute in fur and other forest products to the dominant principalities, especially Novgorod. The importance of river systems and portages to the movement of goods and people has been well demonstrated in this research (Makarov 1997). Makarov has built upon these surveys carried out in the 1990s by intensive investigation around Lake Kubenskoye, recently producing three volumes of results that have used a multidisciplinary approach to address wider landscape and ecological themes (Makarov 2007, 2008, 2009). More recently, he and his team from the Institute of Archaeology in Moscow have turned their attention to the hinterland of Suzdal (Suzdalia) where they have been examining the social elite at rural sites in the area (Makarov 2013).

Turning to ecology, while the study of the animal economy of medieval Russia has lagged

behind that in the West, it has had some notable successes in recent years with studies of both domestic and wild species used to understand the role and type of settlements (e.g., settled agricultural communities versus fur-trapping stations). This work has also provided datable evidence for the decline in the population of certain hunted species such as beaver (Savinetsky and Krylovich 2009). Other zooarchaeological studies have included analyses of the contrast between animal assemblages found at urban and urban-hinterland sites in the Novgorod and Byeloozero regions (Maltby 2012; Brisbane et al. 2015).

Another ecological approach has been to develop models to provide a more detailed understanding of the changes in the composition of the medieval forest brought about by anthropogenic factors and the consequences this had for wildlife (Hamilton-Dyer et al. 2016).

The study of the arrival of Christianity in Russia in CE 989 and the impact of the Church on settlement and social stratification has also gone through various phases of development. In Soviet times, these topics were dealt with, as many topics were during this period, from a largely technological point of view. For instance, studies by archaeologist and architectural historian Pavel Rappoport (1913–1988) on the building of churches within medieval Russia concentrated on the investigation of how people went about constructing them, including topics such as brickmaking, lime firing, roofing, and decoration, as well as how churches were laid out and how much brickwork was required per day (see, e.g., his work on churches in Kievan Russia published in English in 1995) (Rappoport 1995).

More recent studies on the introduction of Christianity into Russia have focused on the material culture of the Church itself in terms of art history and artisan production. The importance of Christianity on settlement and churchyard location is increasingly being recognized as highly significant to settlement patterns of the eleventh to thirteenth centuries, for example, in regional surveys of the Byeloozero region and more recently of Suzdal Opolie (Suzdalia).

Future Directions

Building upon studies of landscape and settlement patterns, the work program established by the Institute of Archaeology, and supported by the Russian Academy of Sciences, has set the agenda for the foreseeable future for medieval archaeology in Russia. Topics include center/periphery relations, settlement patterns, shifting settlements within a landscape (Brisbane et al. 2012), as well as issues of social stratification and the rise of elites. The last of these raises interesting and much-debated questions of where the elites actually reside – in the town or the country – with some archaeologists now challenging the long-held view that towns such as Novgorod were where the *boyars* resided and had their power base. As mentioned above, undefended sites around Suzdal are now being mapped and studied with a view to testing this hypothesis (Makarov 2013).

Another example of one of the Institute's long-term projects that will help to bring new ideas forward is the work being undertaken in the region of Kaliningrad, where a German and Russian team of archaeologists have been undertaking joint surveys and excavations in an attempt to locate the Viking settlement of Wiskiauten (Ibsen and Frenzel 2010). In addition, A.N. Khokhlov is leading a team undertaking large, urban excavations within the city of Kaliningrad (formerly Königsberg), some of the first investigations to be carried out in the city since WWII. These projects are part of a wider initiative for a collaborative study of what was formerly East Prussia, supported by Polish, German, and Lithuanian organizations.

Medieval Urbanism

Keith Lilley
School of Geography, Archaeology and Palaeoecology, Queen's University Belfast, Belfast, Northern Ireland, UK

Introduction

The Middle Ages in Europe was a key period in the continent's urbanization. The proliferation of urban life, especially from 1000 CE to 1300 CE,

shaped the European landscape, physically, economically, and demographically, as population levels increased and a growing commercialization affected all aspects of culture and society. The creation of towns occurred simultaneously with the expansion of older-established urban centers to forge a new map of urban Europe by 1300. At the same time, the fortunes of some towns and cities grew, while others waned, and some disappeared altogether or became villages rather than places with urban functions. The explanations given for these changes in urban fortune range from the following: (1) the importance played by long-distance trade, encompassing both maritime networks and land routes; (2) the role played by aristocratic elites through tenancy and dynastic practices, involving both secular and ecclesiastical lords; and (3) the European-wide expansion and colonization of lands through cultivation and settlement, particularly in areas that were previously marginally occupied, such as uplands, woodlands, and marshlands.

Definition

"Medieval urbanism" is usually defined *functionally* based upon the presence of certain urban characteristics, such as settlements having a greater population size and density, a high proportion of economic activities based on consumption and production, and high levels of administrative status and provision. A further definition concerns *urban form*, for urban landscapes are characteristically more nucleated and physically dense than rural settlements, though where the boundary is drawn between "urban" and "rural" settlement hierarchies is largely dependent on locality, on geography, and on temporal context. An urban place in medieval Europe is more likely also to be distinguishable in terms of its *material culture*, in having a greater variety of imported or exotic ceramics and textiles, for example, while higher levels of consumption of towns and cities are evident in the abundant animal and plant remains usually found in medieval urban archaeological contexts.

Key Issues/Current Debates/Future Directions/Examples

Scholars have long studied medieval towns and cities in Europe, particularly in the field of urban and constitutional history, as well as historical and urban geography. The contribution of archaeology to understanding urban life in the Middle Ages began in earnest after the Second World War, particularly through the redevelopment of war-damaged historic cities. As a result of archaeological study, the documentary-based histories of medieval urbanism have been challenged and in some cases rewritten, for what material culture has shown is a much higher degree of urbanization in Europe in the post-Roman period (400–600 CE) than some historians had previously imagined (see Hodges 1982; Verhulst 1999). Rather than urbanism dying out in the "Dark Ages" in northern Europe, evidence for new trading places occupying coastal and riverine locations has shown not only that there were settlements that have characteristics expected of towns but that these places were linked, through long-distance trade, to urban centers in southern Europe, especially around the Mediterranean. By no means were these new places always defended with palisades or walls, though many urban defenses remained in place around the former Roman towns and cities.

After the fall of the Roman Empire, urban life continued in southern Europe, as evidenced by the continuity in urban form and fabric seen in some Italian cities (Ward Perkins 1988). While a break in urban occupation can be detected archaeologically in some former Roman urban centers in northern Europe, in other cases the evidence instead reveals urban development occurring on new sites, sometimes in locations situated close to former Roman cities, as in the case of Hamwic in southern England (Ottaway 1992). Continuity in urban life across Europe after 400 CE was thus differentiated geographically across the continent, but it would be wrong to see northern Europe being "un-urban" at this time, for the period of 400–600 CE was no "Dark Age" as some past historians have suggested, but rather a period of transformation, a shift from one "urban world" to another. Urbanization also continued to occur

both in the eastern part of the Empire, in what became the Byzantine Empire centered on Constantinople (present-day Istanbul), and in the former western parts, in sub-Roman Europe in Visigothic Spain and Lombardic Italy, for example.

As well as continuities in urban life in the early Middle Ages, there were of course changes, too, as the map of post-Roman urban Europe reflected shifting geopolitics and economic geographies. By 1000 CE the most important urban centers were invariably those with significant religious and ecclesiastical roles, such as the seats of bishops or archbishops, for example, York (England) and Tours (France), as well as those acting as centers of royal or imperial authority, such as seats of kings and emperors, for example, Prague (Czechia) and Aachen (Germany) (Nicholas 2003). The administrative functions of certain cities thus placed them at the center of networks of power, exercising command over large territories and so further serving the interests of those elites who ruled. It was also in this period of the Middle Ages, particularly from the 1100s onward, that Europe saw the most active phase of urbanization, as many new towns were established by aristocratic elites on their rural estates, and urban authorities sought to extend the built-up areas of already existing towns and cities (Lilley 2002). It was this period, in particular, that created the pattern of medieval towns and cities that survives in Europe today, an inherited urban network of huge cultural significance.

By the time of the Black Death in Europe, 1347–1351, the continent had attained its maximum extent and intensity of medieval urbanization. However, although the plague had a significant demographic impact across the continent – in the countryside as well as in the towns – contrary to popular belief, the plague did not completely kill off many towns, but rather initiated another period of urban transformation (Platt 1996). Indeed, with labor demands in the countryside diminished – especially in arable regions – rural-urban migration increased in the fourteenth century, and so the population of towns and cities was swelled by new arrivals, economic migrants, sometimes leading to anxiety among established urban elites (Dyer 2002). Urbanism in medieval Europe across 1,500 years is thus characterized by a complex pattern of continuity *and* change, but whether subjected to major political shifts, as with the fall of the Roman Empire, or demographic crises, as with the Black Death, urbanism in Europe was remarkably resilient throughout the Middle Ages (Ottaway 1992).

The general geographical and historical trends in European medieval urbanism have been fairly well established over recent decades, though one issue that continues to see less than adequate treatment is how medieval towns did grow. In part the reason this fundamental question is difficult to answer is because both documentary and archaeological records usually reveal rather little about who was involved in the creation and development of medieval towns and cities. Written sources from the period tend to reflect the roles and interests of social elites, such as bishops and kings, whose charters granting certain urban privileges have survived and are usually regarded by historians as primary evidence for the activities of certain key authorities in creating towns and in fostering urban development. Yet recent research has shown that the granting of a charter to a town often came quite late in its history, for archaeological traces of urban life can be detected long before a particular place became regarded, constitutionally, as a "borough," an enfranchised town.

One way of writing histories and archaeologies of medieval towns and cities is to study their form, their morphology. This involves looking at the characteristics of street layouts and lot patterns, using large-scale modern maps and plans of medieval towns and cities. Although very few medieval maps of towns survive, modern map-making techniques, when combined with archaeological and documentary study, can be used to map out phases of urbanization that had occurred during the Middle Ages. This is because each phase of urban development is identifiable through particular morphological characteristics, each distinctive in its shape and form and made visible by mapping. Such mapping reveals patterns of physical formation, as towns were extended and expanded over the centuries, during the High Middle Ages especially. The variety of these medieval urban forms is immense and is not

readily divided into particular morphological groups or categories. Indeed, the morphological evidence does not support at all the idea that there were "planned" towns with "regular" forms and "organic" towns with "irregular" forms. Instead, all medieval towns and cities had "composite forms," made up of distinct areas of streets and lots, so that towns such as Coventry (England) – long considered by some to reflect "organic" growth – can be seen to have plans that reflect phases of "planned development" (Lilley 2002) (Fig. 1).

The subject of medieval town planning has tended to focus on the founding of "new towns" or emphasizes the presence of "regularities" in urban form, such as geometrical patterns in a town's streets and street blocks (Schofield and Vince 2003). Planning, however, took many different forms, and even those examples considered to be "new towns," such as Ludlow (England), were not created in one single "planned" episode but rather were developed over longer time periods, resulting in a "composite plan" (like Coventry) (Lilley 2002) (Fig. 2). The subject of "planning" is critical in understanding how medieval towns grew – for it concerns who did what and how. In fact, there were a number of agents involved in shaping urban landscapes in the Middle Ages, from the landed aristocracies and civic elites on whose lands urban development took place to particular specialized individuals, such as surveyors and administrators, who had the necessary expertise to lay out new streets and lots for townspeople, while of course the occupants of towns and cities themselves also shaped urban landscapes, through the buildings they made and the property transactions they conducted. As a process, then, urbanization demands consideration of the roles played by urban agents and the agency that individuals and groups had in shaping the urban worlds around them.

Shaped by a myriad of agents, the resulting urban landscapes were of course ultimately a home to many. How distinguishable one locality in a town or city was compared to another is something that has increasingly interested urban archaeologists and historians, with some describing such differences in terms of the built environment and building types, others focusing more on trades and occupations, or ethnic and cultural identities, as distinguishable traits, while yet others point to different sonic and sensory landscapes. Of course, in the Middle Ages, as now, all of these factors contributed to a *sense of place* in an urban landscape, with some parts of a town seemingly more attractive and appealing to live and work in, while others were deemed more difficult and dangerous (see Goodson et al. 2010). Urban places thus had identities, while the places that townspeople occupied affected how they themselves were seen and perceived by others (Lilley 2002). Particular urban areas acquired reputations from the activities performed in them as well as being reinforced by the social and cultural identities of those who frequented or inhabited them. Areas situated close to trading places, such as quaysides and markets, were often locations where particular "deviant" practices occurred, such as prostitution. Such liminal spaces were places of transitory people – merchants, traders, and sailors – and invariably "edgy." Although attempts were made by urban authorities to expel – or marginalize – such activities, they nevertheless continued.

Cultural identities were thus forged through urban landscapes, of *being* in particular places. For most medieval towns and cities, distinct "neighborhoods" are difficult to define however, either archaeologically or historically. Urban spaces were fluid and the occupants of towns and cities likewise constantly shifting, adding to the *frisson* that characterizes urban life. There were urban communities, of course, fostered through guild associations for crafts or religious institutions, for example, but these were not localized socially except through particular structures such as guildhalls. Nevertheless, certain areas of medieval towns and cities were associated with particular kinds of economic or administrative activity, such as sites of trading, production, or ceremonial practices. Within these areas a multitude of activities would still take place, and housing would be a mixture of dwellings for rich and poor (Beattie et al. 2003). A complex pattern of households existed so even within one individual building different rooms might be lent to

Medieval Urbanism, Fig. 1 The pattern of urban development of medieval Coventry (England) as mapped by Lilley (2002)

M

journeymen as well as families. The buildings of a medieval "tenement" would generally occupy the street frontage, consisting of workshops and shops at ground level, with rooms for living in both above and behind (Schofield and Vince 2003). To suggest there were rich and poor neighborhoods in medieval towns is therefore an oversimplification. Instead, a sense of locality and community was formed through neighborhood ties and identities defined and mediated through rituals and ceremonies, worship in parish churches serving particular urban areas, for example, and annual activities such as feast days and processions (Hanawalt and Reyerson 1994; Boone and Stabel 2000).

Understanding the social and cultural dimensions of medieval urban life, "community," and "neighborhood" relations, for example, has gained much from recent cross-disciplinary studies of medieval towns and cities, combining different approaches. The blurring of boundaries (often drawn by past historians such as Henri Pirenne and Edith Ennen) between medieval urban and rural communities has similarly benefitted from multidisciplinary studies, for it has become clear, increasingly, that town and countryside in the Middle Ages were intimately connected (Giles and Dyer 2005). Indeed, one of the recent trends of exploring medieval urbanism is to think about towns and cities *spatially*, not only in terms of their geographical locations and interconnections through networks but more subtly through the close interrelationships between people and places (Classen 2009). For instance, the places of the urban poor, Jews, and women in medieval towns and cities have all been thoughtfully examined by archaeologists, historians, and geographers through evaluating various kinds of textual, artistic, and material evidence and revealing the multifaceted and multidimensional qualities of urban life in the Middle Ages (Goodson et al. 2010).

The recent "spatial turn" influencing humanities and social science research and broader intellectual currents such as post-colonialism and gender studies (Wallace 2004) have helped enrich a more empathetic and nuanced appreciation of medieval urbanism. Yet despite the current critical reevaluation of medieval urban life, through adopting new approaches and ideas, the medieval town and city are all too often still considered in isolation. In isolation, that is, from other times and places, in relation to a broader comparative context and a larger history of globalism, of Western, European encounter and expansion. Medieval Europe did not function in a vacuum and neither did its towns and cities (Platt 1979). Instead, its people and its urban centers were part of a wider world of networks and flows, of mobile bodies, ideas, artifacts, commodities, and cultures (see Lev 2002). There exists much scope therefore to look again at the material culture of medieval urbanism, and explore its global as well as local contexts, and establish what this might mean for global histories and archaeologies. The port city of Bristol, for example, in the late fifteenth century, was a key focal point of networks that stretched not only across and around the Mediterranean and Atlantic seaboard of Europe but crossing the Atlantic too, to Iceland and North America (Quinn 1974). Similarly, Portuguese towns and cities of the later Middle Ages functioned as part of an international maritime network that connected Europe with Africa and Asia and potentially even Australasia (Abulafia 2008).

One of the future challenges in the study of medieval urbanism, then, is not only to analyze what was happening within European towns and cities during the Middle Ages but also to look beyond Europe too, to the wider world. In so doing, exploring comparisons and connections between medieval towns and cities at a global scale, there is scope to rethink medieval urbanism and assure its continued place in global archaeology.

Mediterranean Sea: Maritime Archaeology

Emad Khalil
Centre for Maritime Archaeology, Faculty of Arts, Alexandria University, Alexandria, Egypt

Introduction

The history and development of Maritime Archaeology as a scientific discipline is closely related to the Mediterranean Sea, which has been a witness to some of the oldest civilizations in the world. Along its shores flourishes the Ancient Egyptian, the Phoenician, the Greek, the Roman, the Byzantine, and the Islamic civilizations (Norwich 2007; Scarre and Fagan 2008). Accordingly, throughout the ages, maritime activities played a major role in the rise, development, and decline of such civilizations and societies. On the other hand, their maritime activities have left an array of material cultural evidence, which mainly takes the form of shipwrecks, harbors, and other waterfront installations.

Since the beginning of the twentieth century, the discovery of submerged archaeological sites in the Mediterranean triggered studies in maritime and underwater archaeology in different regions and countries, subsequently, the field of maritime archaeology in the Mediterranean witnessed substantial development on different levels including research, education, preservation, and public presentation.

Definition

It is quite essential, at first, to define Maritime Archaeology, which is the subdiscipline of

archaeology concerned with the study of maritime cultural heritage. It mainly includes the study of different types of watercrafts, as well as the study of coastal installations, whether these were found on land or underwater. Maritime Archaeology is not the same as underwater archaeology, which describes the study of the past through any submerged remains (Muckelroy 1978: 3–10). In other words, there are maritime archaeological sites which are not located underwater, such as ship burials, and there are submerged remains which are not of a maritime nature, such as jettisoned cargoes. However, it is evident that shipwrecks are the most common type of maritime archaeological sites; therefore, the development of maritime archaeology in the Mediterranean is often associated with the investigation and study of shipwrecks. On the other hand, maritime archaeology contributed significantly to the development of different studies such as ancient ship construction, ancient seafaring, and harbor archaeology. This entry will be looking at the development of maritime archaeological investigation which has been carried out along the shores and under the waters of the Mediterranean Sea.

Historical Background

Maritime Archaeology in the Mediterranean has gone through different phases of development which started as simple salvage operations and the recovery of submerged objects for their artistic, cultural, or monetary values. Sponge divers, in particular, have often encountered many ancient shipwrecks, and in most cases mounds of amphora and pieces of wood were of little or no interest to the sponge seekers. However, in 1900, sponge divers discovered near the Greek island of Antikythera the remains of an early first-century BC shipwreck at a depth of 55 m. The ship was carrying bronze and marble works of art, in addition to several pottery and glass items. The discovery of the shipwreck caught the attention of the Greek authorities who decided to salvage the ship's cargo for its artistic and historical value. The project was directed by the Greek antiquities authorities; however, the underwater work was exclusively carried out by helmet sponge divers (Throckmorton 1991: 16–20).

Another significant step in the development of maritime archaeology in the Mediterranean was the excavation of the Lake Nemi vessels in Italy. Since the fifteenth century, there have been several attempts to salvage the two large Early Roman vessels, submerged in Lake Nemi south of Rome. However, between 1928 and 1931, on the orders of the Italian dictator Benito Mussolini, the lake was drained using powerful pumps to expose the two immense and lavishly decorated vessels from the time of the Roman emperor Caligula. Nonetheless, the motive behind the project was political and nationalistic rather than archaeological (Blot 1996: 38–41).

The development of the Self-Contained Underwater Breathing Apparatus (SCUBA) in 1946 by Emile Gagnan and Jacques-Yves Cousteau (Joiner 2001: 1.3–1.4) represented a breakthrough in underwater exploration, which was reflected on the development of underwater archaeology. Between 1952 and 1957 Cousteau and his team of divers excavated a Roman shipwreck site at the foot of the rocky island of Grand Congloué, off Marseille. During the project numerous equipment and techniques were experimented and developed for underwater excavation; such techniques are now considered standard in many underwater archaeological projects. However, the Grand Congloué excavation witnessed some serious methodological problems, due to the limited involvement of archaeologists in the project, which resulted, at that time, in the misinterpretation of the site (Sibella 1997: 174–175). Another significant stage in the development of Maritime Archaeology in the Mediterranean was the excavation of the Albenga Roman shipwreck by the Italian archaeologist Nino Lamboglia, between 1961 and 1971. In addition to its archaeological importance as one of the largest Roman shipwrecks found in the Mediterranean, the Albenga shipwreck excavation was directed by an archaeologist, and a number of archaeologists contributed to the study of the excavated material. However, Lamboglia did not think that archaeologists should dive, so none of the archaeologists involved in the project dived on the site. Rather,

they remained on surface, managing the excavation remotely and interviewing the divers who collected the artifacts to try to establish their provenance (Carlson 2011: 382).

Perhaps a key turning point in the history of Maritime Archaeology in the Mediterranean took place in the 1960s. It was during that decade that the first scientific underwater excavations took place, and publications about the theory and practice of underwater archaeology started to appear (Dumas 1962; Frost 1963; Taylor 1965; Bass 1966; Throckmorton 1969).

In the 1960s, the excavation of the Late Bronze Age shipwreck off southern Turkey's Cape Gelidonya was the first underwater archaeological project to be carried out according to archaeological scientific standards. The site was originally discovered by Turkish sponge divers. However, it was excavated by a team of sport divers and amateur archaeologists led by the pioneer maritime archaeologist George Bass. The Cape Gelidonya shipwreck was the first one to be excavated entirely underwater and it proved that underwater archaeological sites could be excavated and studied as rigorously as terrestrial sites and according to the same archaeological standards (Bass 2005: 48–55). In the following years, Bass published his first book, which discussed several theoretical, methodological, and practical aspects of conducting archaeological work underwater (Bass 1966). In addition to the study of ancient shipwrecks, the study of harbors and submerged landscapes also started developing in the 1960s and 1970s (Flemming 1971). The work that Honor Frost did was probably the first in that respect in the Mediterranean. She was a pioneer female underwater archaeologist who had worked with Bass on the Cape Gelidonya shipwreck. She had a special interest in the study of anchors and harbors in the Eastern Mediterranean and had worked extensively in the Levantine coast. Her 1963 book was the first to discuss different aspects of harbor and port archaeology in that region (Frost 1963).

Perhaps, one of the most important publications which represented international recognition for the new field of underwater archaeology was *Underwater Archaeology: A Nascent Discipline* (UNESCO 1972). Not only it contained contributions from a number of archaeologists presenting different maritime and underwater sites, but also it discussed an array of archaeological, methodological, and technical aspects of maritime and underwater archaeology.

The foundation of the Institute of Nautical Archaeology (INA) in 1973 by George Bass and a number of his colleagues was a major step in maritime archaeological research in the Mediterranean. Since then, the INA has carried out numerous surveys and excavations in different Mediterranean countries. It also has contributed to training many archaeologists from those countries in aspects of underwater archaeology. The INA also contributed to the creation of one of the earliest museums of underwater archaeology, the Bodrum Museum of Underwater Archaeology in Turkey.

Few years following the UNESCO 1972 publication, one of the most important volumes on maritime archaeology was published (Muckelroy 1978). In addition to discussing different types of sites and the special qualities of underwater archaeology, the book presented, for the first time, a theoretical framework for the formation of underwater archaeological sites. Muckelroy's contribution has been the basis upon which numerous further studies and discussions were based. His volume is still considered a turning point in the development of maritime archaeology.

Key Issues/Current Debates

For the past 50 years, hundreds of sites were discovered and numerous surveys and excavations were carried out for different types of maritime and underwater archaeology sites all over the Mediterranean (Parker 1992). Accordingly, the field of maritime archaeology witnessed substantial development, particularly from a methodological and technological perspective (Green 2004). Advanced technology used for underwater archaeological investigation, such as underwater acoustics, and underwater imagery techniques became widespread and readily available for

researchers and institutions working in underwater archaeology. Moreover, during the past two decades the investigation and study of underwater archaeological sites in deep water using remote sensing techniques became quite common in several northern Mediterranean regions (Ballard et al. 2000; Wachsmann 2011). Despite its high cost, these projects proved the possibility of exploring underwater sites beyond diving limits, using non-intrusive methods, especially since the sites located in deep waters are often in a good preservation condition.

However, the large number of underwater archaeological excavations which took place in the Mediterranean during the past five decades yielded thousands of artifacts of different types, materials, and dates, which required extensive resources for conservation, storage, and display. Therefore, maritime museums and museums for underwater archaeology have been established in a number of Mediterranean countries, mainly to display material culture which has been excavated from underwater. It is worth mentioning, however, that there is a complete absence of maritime museums in most southern and eastern Mediterranean countries, which has negatively affected public awareness of maritime and underwater archaeology in that region.

Despite the existence of specialized conservation facilities and maritime museums in several Mediterranean countries, it became evident that underwater archaeology is significantly costly and time-consuming, not only for the excavation phase but also mainly for the conservation and management of the excavated material (Robinson 1998: 11).

Shipwreck excavations in the Mediterranean often come across submerged cargoes that include tens, hundreds, hundreds, and sometimes thousands of amphorae. Raising them and hence providing storage often represents a serious challenge for the museums. On the other hand, the conservation of organic material such as ship timbers could take many years to be accomplished, which requires considerable financial and material resources.

Therefore, during the past decade, there has been an evident change of concepts in underwater archaeology, from excavations and retrieving of artifacts to the management and in situ preservation of submerged archaeological sites. It was realized that excavations are not always the best ways for dealing with underwater archaeological sites and that there are other options which are more preferable in many cases. The UNESCO (2001) Convention on the Protection of the Underwater Cultural Heritage asserts that "the in situ preservation of underwater cultural heritage shall be considered as the first option before allowing or engaging in any activities directed at this heritage." Therefore, there has been an international trend towards the preservation of underwater archaeological sites where they are found and more focus in being put on underwater surveys and mapping of sites rather than full excavations. Accordingly, several northern Mediterranean countries are conducting large-scale surveys and mapping projects of their coasts in order to assess their maritime archaeological resources and develop methods for protecting and preserving them. On the other hand, different methods and techniques for the in situ preservation of underwater sites have been developed and tested in Mediterranean countries (Zmaić 2009). However, in situ preservation of underwater archaeological sites raised another issue concerning the presentation of those sites to the public. How can the sites be protected in situ and yet be available for public enjoyment and education? The options were either to bring the visitors physically to underwater sites or to bring these sites virtually to the visitors. The first option is represented by underwater archaeological parks and cultural dive trails which have been developed in some Mediterranean countries such as in Italy, Croatia, Greece, Turkey, and Israel. This mainly targets the diving community which forms the majority of the visiting public to these types of sites. On the other hand, the great development in information technology and digital imaging has enabled transmitting information about the underwater archaeological sites to the wide public through virtual reality images, 3D projections, and holographic displays; all can be utilized in museums to bring the underwater sites to the public (Manders 2008: 35–39).

Another aspect of maritime archaeology which has witnessed a significant development in the past years in Mediterranean countries is education and training. A number of Mediterranean countries have introduced studies in different aspects of maritime and underwater archaeology into their university curricula (UNESCO 2010). Also several countries, such as Turkey, Egypt, Croatia, Malta, and Spain, in collaboration with the UNESCO, have organized workshops and training programs in underwater archaeology and the conservation of underwater finds. This has significantly contributed to building capacity in that field.

Finally, in most Mediterranean countries, there are currently dedicated units within the national archaeology authorities specialized in underwater cultural heritage. Such units are normally responsible not only for conducting underwater archaeological projects within their respective countries, but also for overseeing and organizing work done by other archaeological missions or groups working within the countries' territorial waters.

International Perspectives

The development of maritime and underwater archaeology in Egypt has not differed significantly from other Mediterranean regions (Khalil and Mostafa 2002). However, one of the earlier discoveries in that field took place in the desert rather than underwater. In 1894, at least five boats from the Middle Egyptian Kingdom were found at Dashur south of Cairo (Haldane 2000: 83–102). The discovery of the Dashur boats could be considered the beginning of maritime archaeology in Egypt. It was followed by the discovery of several other boat and ship burials such as the Old Kingdom royal ships of Khufu in 1954 and the Early Dynastic boats of Abydos in 1991 (Haldane 2000: 39–43, 45–60).

Nevertheless, underwater archaeology in Egypt can be generally divided into two phases. The first phase started at the beginning of the twentieth century with the efforts of sport divers and amateur archaeologists, and it is mainly characterized by accidental discovery of underwater archaeological sites in the Alexandria region and hence the subsequent salvage operations which were carried out at those sites. The most important discoveries of that period were the pre-Hellenistic harbor of Pharos in 1912 and the submerged remains of the ancient lighthouse of Alexandria in the 1960s (Morcos 2000). The second phase of underwater archaeological research in Egypt started in the mid-1990s with two significant projects: the excavation of the submerged remains of the ancient Pharos lighthouse of Alexandria (La Riche 1996) and the excavation of submerged Ptolemaic royal quarters at the Eastern Harbor of Alexandria (Goddio et al. 1998). In addition to the archaeological value and significance of those two projects, they have shed light on the potentials of underwater archaeology in Egypt and opened the door to many projects that took place in the Alexandria region. However, it is worth mentioning that all the underwater archaeological research that took place in Alexandria has been concerned with submerged structures and landscape rather than shipwrecks. Nonetheless, a major drawback in underwater archaeology in the Egyptian Mediterranean waters is that it almost entirely focused on Alexandria, with very limited projects conducted elsewhere. Moreover, the Egyptian contribution to such projects was quite limited as the work was mainly carried out by foreign teams, yet the projects provided a great opportunity for training young Egyptian archaeologists on different aspects of underwater archaeology, which led to the establishment of the Department for Underwater Archaeology (DUA) in 1996 as part of the Egyptian Supreme Council of Antiquities (SCA), the authority responsible for overseeing all archaeological work in Egypt. The establishment of the DUA was a governmental recognition of the significance of underwater archaeological research in Egypt.

In addition to the archaeological projects that took place under Egyptian waters, a number of other important maritime sites were discovered and studied along the shores of Lake Mareotis

west of Alexandria. This included some of the most significant lake harbors and lacustrine waterfront structures in the Mediterranean (Blue 2010; Blue and Khalil 2011).

Nonetheless, a major problem in maritime archaeology in Egypt is related to its public presentation and appreciation. Despite its long and significant history, and the number of maritime archaeological sites that have been investigated, Egypt does not have a maritime museum, and the public presentation of maritime and underwater archaeology is insignificant, which has several shortcomings related to public awareness and knowledge of the Egyptian maritime cultural heritage. Nevertheless, Egypt has excelled in specialized education in Maritime Archaeology with the establishment of the Alexandria Centre for Maritime Archaeology and Underwater Cultural Heritage in 2009 as the first academic center in the Southern Mediterranean concerned with providing education and training at different levels in aspects of that field. The center targets students from Egypt, the Mediterranean, and the Arab Region; therefore, the education and training that the center provides would contribute to the development of maritime and underwater archaeology by creating generations of educated and trained maritime archaeologists.

Future Directions

It is evident that maritime and underwater archaeology in the Mediterranean has gone through different stages of conceptual, methodological, and technical development since the 1960s. Turning away from complete excavations of specific sites to surveying and mapping of large areas have been a distinctive feature of numerous projects that took place during the past decade. However, it is expected that the future will be characterized by multinational projects that are carried out between several countries and which emphasize on specific aspects related to maritime archaeology such as preservation, capacity building, and cultural tourism. Some EU-funded projects, which have already been initiated, were associated with underwater archaeology, such as the Project on Integrated Maritime Policy for the Mediterranean (IMP-MED), which is part of the European Neighbourhood and Partnership Instrument (ENPI), and also the EU (Tempus) Program, which funded the creation of the Alexandria Centre for Maritime Archaeology and Underwater Cultural Heritage in Egypt. On the other hand, the UNESCO secretariat of the Convention on the Protection of Underwater Cultural Heritage has been very active in collaborating with different Mediterranean countries, especially in disseminating the ideas and principles of preservation and public education. During the coming years, the EU will hopefully play an even greater role in funding projects related to site management, education, and training in maritime archaeology in the Mediterranean region. On the other hand, it is expected that more research projects will be carried out in deep and international waters. These are getting more and more accessible with the advances in remote sensing technology, particularly the use of the Autonomous Underwater Vehicles (AUV). Furthermore, in countries where maritime archaeology is still a nascent discipline, such as most Mediterranean Arab Countries, it is anticipated that such countries will put more emphases on the exploration and hence the preservation and public presentation of their cultural heritage. Also regional collaboration in education and training of maritime archaeologists has started and is expected to develop further in the future especially between countries witnessing recent political changes.

Meehan, Betty

Sally Brockwell
Australian National University, Canberra, ACT, Australia

Basic Biographical Information

Betty Francis Meehan was born in Bourke, New South Wales, Australia, in 1933 and grew up there, the elder daughter of Francis Owen and Olive Jane Meehan. After completing high school in Bourke, she trained as a specialist infants teacher at Bathurst Teachers College and later taught in Sydney, Bourke, Darwin, and Canberra. In 1958, she travelled to Arnhem Land in northern Australia, accompanying her first husband, the late Lester Richard Hiatt, on fieldwork for his anthropology Ph.D. There she set up the first school for Aboriginal children at Maningrida. She went on to study at the University of Sydney and gained a Bachelor of Arts (Hons) and Master of Arts (Hons) in anthropology. In 1972, she enrolled in a Ph.D. in the Department of Prehistory and Anthropology at the Australian National University (ANU) in Canberra and returned to Arnhem Land for her fieldwork with her second husband, collaborator, and colleague, the late Rhys Maengwyn Jones. She graduated in 1975 (Fig. 1).

Betty's Ph.D. thesis became the basis for her iconic book *Shell Bed to Shell Midden* (Meehan 1982) for which she became internationally famous. The book describes the role of shellfish and a year in the life of the An-barra people of the Blyth River and has influenced generations of scholars from ethno-archaeologists to gastronomists. The fieldwork on which this book is based was done with the enthusiastic collaboration of Betty and Rhys' An-barra family – Frank Gurrmanamana and Nancy Bandeiyama (both now deceased) and their extended family.

Betty joined the Department of Prehistory in the Research School of Pacific Studies at the Australian National University as a Research Fellow in 1977. She continued her ethno-archaeological investigations in Arnhem Land and worked as an anthropologist with Athol Chase on the Upper Daly Land Claim in the

Meehan, Betty, Fig. 1 Betty Meehan collecting shellfish (*Marcia hiantina*) from shell beds off the beach near the An-barra home base Lalarr Gu-jirrapa where she and her husband Rhys Jones lived for seven months in 1973. (Photo taken by Rhys Jones, wet season, early 1973)

Northern Territory. In 1985, she joined the Division of Anthropology at the Australian Museum (AM) in Sydney where she carried out research on Aboriginal material culture in northeastern and central Arnhem Land and on the Daly River in the Northern Territory. This research was funded by the Australian Research Council, and detailed reports were lodged with that agency and the AM. From 1990 to 1991, she was Head of the Aboriginal Section in the Collections Management Division, National Museum of Australia in Canberra. In 1991, she joined the Australian Heritage Commission as Director of the Aboriginal and Torres Strait Islander Section where, as part of her responsibilities, she coordinated several National Indigenous Heritage Art Awards. After retirement, Betty has continued to work on her An-barra Archaeological Project in collaboration with Sally Brockwell of the ANU. A major monograph is planned for this research. Betty Ngurrabangurraba, daughter of Frank Gurrmanamana and Nancy Bandeiyama, is collaborating with Betty Meehan and Sally Brockwell in order to complete this work (e.g., Brockwell et al. 2005).

Major Accomplishments

Betty has been an inspirational influence in her dual professions of archaeologist and cultural anthropologist, as researcher, fieldworker, ethnographer, teacher, editor, collector, and curator. Her research has touched on many themes in Indigenous society: the role of women, diet and nutrition, art (including organizing numerous exhibitions), material culture, heritage studies, ecology, demography, and contemporary issues. She has published extensively on her research in Arnhem Land and elsewhere (e.g., Hiatt 1967–68; Meehan 1977, 1991; Meehan and Jones 1980, 2005; Hiatt et al. 2002). She is a life member of the Australian Archaeological Association for her outstanding contributions, a Fellow of the Australian Academy of Humanities, and a member of the Australian Institute of Aboriginal and Torres Strait Islander Studies.

Introduction

By the mid-fifth millennium BCE, Neolithic communities along the Atlantic Seaboard of Europe began to witness the emergence of a pictographic language based on a common repertoire of abstract and figurative motifs. This distinct art form is arguably an extension of a much wider pan-European schematic art tradition which was mainly confined to communities involved in passage grave construction and use. The megalithic art tradition unified much of the Neolithic world along the coastal regions of the Mediterranean and the Atlantic coastal fringes of Europe, between the Iberian Peninsula and northern Scotland for a period of some 3,000 years and account for around 10–15% of all extant monuments. The art itself appears to have acted as a personal signature that was unique to each monument and its builders but drawn upon a limited set of symbols that included chevrons, concentric circles, cupules, spirals, and zig zag lines. The majority of this repertoire was engraved, although there is clear evidence that many sites were also painted. Recognized along the Mediterranean and Atlantic coastal fringes are around eight core areas; of these, four are islands. Each area appears to have had its own unique and distinct artistic autonomous repertoire, possible representing regional identity.

Definition

It is not entirely clear where and how megalithic art originated, although controversially it appears to form part of a much larger Schematic art tradition, itself having origins in the Late Meso-lithic/Early Neolithic of central and western Mediterranean Europe (Fig. 1). Schematic art, forming part of a post-Paleolithic rock art tradition is the term given to both engraved and painted rock art that dates between the fifth and first millennium BCE. Much of what is termed Schematic art is located within southern Europe, in particular, in cave and rock-shelter sites of the Iberian Peninsula. Apart from what is present on the wall so frock-shelters and caves, this artistic tradition also occurred as a portable assemblage, usually decoration on stone and ceramic items such as pendant sand pottery vessels. The height of this significant tradition appears to coincide with Europe's first metallurgists, Copper Age [Chalcolithic] cultures (3500–1700 BCE (dates vary across Europe)), and extends into the Bronze Age (2500–900 BCE (dates vary across Europe)) and probably the Early Iron Age (1200–600 BCE (dates vary across Europe)) as well. Arguably, one of its derivatives is megalithic art which comprises mainly abstract carved and sometimes painted motifs, exclusively associated with Neolithic burial–ritual monuments. It is usually closely associated with the passage grave tradition and decorated pottery (e.g., grooved ware which is common at many sites within Atlantic Europe) which incorporates variations of motifs that are found in megalithic art, such as horizontal bands, chevrons, and lozenges. There are instances though were certain megalithic art designs occur on other monument types such as Portal Dolmens.

In north western Europe, this artistic style has been extensively studied by Elizabeth Shee-Twohig (1981), as well as being the subject of a number of regional and individual site studies

Megalithic Art: A Visual Repertoire for the Dead, Fig. 1 Map of Europe showing the likely chronological spread of megalithic art through the Neolithic world

(O'Kelly 1982; Eogan 1986; O'Sullivan 1986; Lynch 1991; Nash et al. 2005; Nash 2010). Elsewhere, megalithic art has been confused with open-air rock art which occurs later in the prehistoric sequence and usually located within upland areas, away from the burial monuments that usually occupy the coastal fringes of the western Mediterranean and Atlantic Europe (Cunliffe 2001).

Rudimentary studies during the early to mid-twentieth century by the Abbé Henri Breuil and O.G. S. Crawford promoted the idea that the art represented various parts of the human body, in particular the face, which had morphed through time, from Breuil's "stylized mortal" to Crawford's "eye goddess." Not surprisingly, many influences had originated from studies on Upper Paleolithic art by Breuil and German researcher Hugo Obermaier. During this period, Breuil considered that there was a direct link between megalithic art within the passage graves and open-air art,

Megalithic Art: A Visual Repertoire for the Dead, Fig. 2 Shee-Twohig's motif classification (1981: 107, Fig. 11)

engraved on to rock out cropping. However, it is now considered that open-air rock art was being executed between 3000 and 1500 BCE, over 1,000 years later than the engraving found in passage graves (Bradley et al. 2001: 496).

Elizabeth Shee-Twohig's (1981) seminal work identified a clear repertoire of motifs that include 11 generic forms, ranging from chevrons, lozenges, and cup-and-rings to zig zags and simple cupules (Fig. 2). In addition to this abstract repertoire and depending on regionality, representative engravings are also present and include footprints, complete – or parts of – stylized anthropomorphic and zoomorphic representations with associated weaponry; however, these motifs may be later additions to an already well-established abstract tradition (Nash 2013). In southern Europe, one can postulate an association between megalithic art and statue stele (menhirs), where stylized anthropomorphic figures are pecked alongside multiple zoomorphic figures and weaponry onto hewn stone and boulders. Here, Bradley (2009: 93) has drawn a clear link between statue stele and burial–ritual monuments, which collectively would have formed part of a complex ritualized landscape.

Ritualized landscapes can take many forms; their intensity could have been based on where burial monuments were sited and their relationship with other nonburial structures such as

Megalithic Art: A Visual Repertoire for the Dead, Fig. 3 The epitome of being Neolithic–looking at New grange from south of the Boyne River. (Author)

standing stones (menhirs) and stone rows. There are a small number of passage graves where megalithic art is carved externally, either onto kerb stones or within the fac¸ade, for example, the three Boyne Valley passage grave complexes of New grange (Fig. 3), Knowth, and Dowth. Here, the art appears to act as a point of reference between space that is known and the fore boding of the long dark passage and the unknown spaces beyond. These public expressions of ritualized rock art production are, however, few in number. The carved art is generally strategically placed within the inner passage and chamber areas where visual access would have been restricted to possibly elites or religious actors within the community. With some monuments, the art faces into the mound or is carved onto the back wall of the ante chamber where its intentional positioning appears to be reserved for the incoming dead and for the ancestors (e.g., the passage graves of D'Er Grahand Gavrinis, Brittany). The carvings within the inner passage and chamber may have represented physical markers where by the art played a vital role in how the dead changed physically and metaphysically as they moved from one area of the monument to another. The position of such art would have also had an impact on those people allowed to accompany the dead to their resting place.

There are distinct differences in panel distribution, motif style, and association between various core areas; it would appear that certain symbols vary in significance according to where in the Neolithic world they appear, each dominant motif setting a trend. In Ireland, for example, two clear primary stylistic repertoires, including curvilinear and angular forms, are present in different monuments, such as the Late Neolithic Irish passage graves of Four knocks I, Knowth, and nearby New grange, County Meath (O'Kelly 1982; Eogan 1986). Spirals are common in the western Mediterranean, Ireland, and western mainland Britain but less so in Brittany. Similarly, radial motifs frequently occur in Brittany but are somewhat rarer elsewhere in Atlantic Europe. These potent signatures, the majority of which are incorporated into the monument's architecture, probably served as a reminder to both the living and the dead of their ancestral past, thereby enhancing a sense of ancestral belonging; the art being clearly associated with death. It is interesting to note that megalithic art does not occur outside the visual draw of these monuments; the majority of motifs are hidden, usually within the inner passage or the chamber areas of the monument. Megalithic art placed on curbing around the mound structure at New grange, Knowth, and Dowth in the Boyne Valley and Lough crew, County Meath, Ireland, may be interpreted as public symbols (O'Sullivan 1986, 1993). However, all three monuments stand within a defined ritual landscape – on a bow of the River Boyne – and as such, the art could only have been viewed from a point within this ritual area, probably by chosen individuals or the elite. From the south bank of Boyne, on lookers would have seen the monument but not its secret art (Fig. 3).

The Interplay Between Art and Architecture

Certain features of passage grave architecture appear to influence the siting of megalithic art, especially within the internal space of the monument. Rarely are these symbols visible from the entrance or fac¸ade; they remain hidden until access into the monument provides an intimate and discrete viewing. Such restricted visual access entails a number of architectural devices intended to heighten the secrecy surrounding the production and use of the engraved and painted art. Many passage graves, for example, possess door and sill stones positioned either side of the passage (e.g., Casa del Romeral, Malaga, Spain), and in some cases threshold stones are also used, arguably to define a point of separation between the world of the living and the realm of the dead. Deliberate kinks in the passage also served to restrict visual access and, in some cases, additionally controlled the amount of light penetrating the passage and illuminating the rear wall of the chamber at the summer equinox and winter solstice, undoubtedly significant annual events of immense symbolic importance.

During the early to mid-fourth millennium BCE, carving within burial monuments appears to have been taken up with vigor in Brittany. This tradition flourished for over a 1,000 years. Along with engraving, Neolithic communities appear to have been in creative competition with their neighbors, attested by the construction of large monumental structures that delineate entire landscapes rather than a specific locale. Le Grand Menhir Brisé once standing over 20 m high and weighing an estimated 280 t stood in full view as a focal point for the passage graves of Table des Marchands and D'Er Grah, both of which contain megalithic art. Several kilometers from this complex is the most elaborately decorated of all passage graves, the site of Gavrinis. Dating to c. 3500 BCE and now situated on an island, each of its passage and chamber uprights is mainly engraved with elaborate abstract imagery. Also present are representative polished stone-axe depictions, repeated and overlapping concentric circles, and curvilinear motifs (Fig. 4). Although this and other monuments elsewhere adhere to a convention in terms of architectural and landscape grammar, the artistic repertoire contains a set of designs and motifs that are regionally unique. These are individually and collectively dispersed around various hidden areas of the monument. Consistent with ideas of ritual concealment and secrecy, the panels may have been intentionally turned inward, facing the internal space of the monument, and thus would have only been perceptible to the spirits of the dead who would have occupied such spaces. Such a practice appears to be an Atlantic coastal tradition with clear in situ in-turned decorated kerbstones at sites such as Newgrange, Knowth, Dowth, and the now destroyed Calder stones monument in northwest England. However, this process appears to have originated around the Gulf of Morbihan at sites that include Gavrinis and nearby D'Er Grah. In the ceilings of both monuments are two broken sections of an enormous 10 m long menhir. Originally this structure would have stood proud within an earlier ritualized landscape. Engraved on one of its surfaces were two goats and a large

Megalithic Art: A Visual Repertoire for the Dead, Fig. 4 One of the highly decorated uprights within the passage of Gavrin is Brittany, France. (Author)

axe symbol. A section that included the axe symbol was incorporated into the passage grave of Table des Marchands (Le Roux 2006). The destruction of the menhir and its integration within the ceilings of the three passage graves may represent a deliberate act of incorporation, drawing the ritual power of an earlier monument into the body of its successor. Gavrinis and other Breton monuments presumably provided an impetus for the erection of truly monumental structures elsewhere in the Atlantic region of northwestern Europe, as attested by the examples of New grange, Knowth, and Dowth in the Boyne Valley, Ireland, Le Déhus and La Gran'mère du Chimquière in Guernsey, and La Hougue Bie in Jersey. However, the number of sites in Ireland and Britain incorporating megalithic art is relatively small and less elaborate in composition.

In most instances the carving on one upright stone rather than another appears to have been a deliberate and intentional act. Based on several well-preserved monuments, megalithic art was only read from the passage or chamber and is thus revelatory in its positioning. At Gavrinis, in the Gulf of Morbihan, 23 of the 29 uprights that construct the chamber and passage are highly decorated, though only some are visible from the entrance looking toward the chamber. However, despite the visibility of those uprights positioned closer to the entrance, the narrative of the other upright panels appears, from this viewpoint, as distorted and virtually impossible to read; the audience is forced to read each stone, probably sequentially (like the chapters in a book). Similarly, visual access is completely restricted at nearby Les Pierres Plates passage grave in Locmariaquer, where 13 decorated uprights occur 5 m beyond the entrance and beyond a kink of some 50° inside the chamber. The hidden art in this monument includes a stylized anthropomorphic "rib-cage" design (Thomas and Tilley 1993). It is argued that this and other abstract forms could not have been viewed by the uninitiated; that is, the majority of the community that would have congregated outside the monument, within the facade area. These people would been excluded from this most secretiveness of the engraved narrative. Instead, the art would have been exclusively read by special individuals who would have had direct contact between the community and the mortal remains of the dead and the spirits that would have inhabited the inner recesses of the monument.

The Potency of the Painted Motif

Although megalithic art is usually engraved, there are a number of sites in southern Europe, exhibiting irrefutable evidence of painting, either as a separate entity or as a combination of painting and engraving. The first discoveries of painted megalithic art were made during the turn of the twentieth century at Dolmen de Dombate (in Portugal) and Forno dos Mouros (in northwest Spain). At Pedra Cuberta, near La Coruña, the uprights in both the chamber and passage were decorated using black, red, and white pigmentation to create chevrons and multiple zig zag motifs (Rodríguez Casal 1990). More recently, field work at the Dolmen de Dombate shows that painted motifs covered most of the internal walls of the monument. It was deduced that both the red and black geometric forms had been painted over a prepared white-painted surface, thus creating a striking yet secretive visual impact upon those few who would have entered this realm of the dead. Red- and black-painted zig zags, at Coto dos Mouros and at Forno dos Mouros, confirm the wide geographic spread of this phenomenon through the northern and western coastal fringes of Portugal and Spain.

Painted motifs, using the artistic repertoire of the megalithic tradition, appear to be a southern European trait, although this trend may have been biased by taphonomic processes, as evidence from elsewhere may not have survived the archaeological record. However, painted motifs that can be relatively dated have been found on megalithic tombs in Malta, Sardinia, and the coastal regions of the Iberian Peninsula (Arosio et al. 2011). Charcoal fragments found within stratified deposits abutting the passage wall at Antelas Viseuin Portugal have revealed a radiocarbon determination of 4,655 $\pm$ 65 BP (Castro et al. 1957), while a further six megalithic sites have been dated in Galicia, north western Spain, using AMS radio-carbon and plasma-oxidation extraction techniques (Freddo

Megalithic Art: A Visual Repertoire for the Dead, Fig. 5 The painted spirals at Tomba Della Scacchiera, NW Sardinia. (Image: Antonello Porcu)

2007). Although the paintings on these monuments are now extremely faint, a number of characteristic geometric patterns can be recognized.

At the recently excavated rock-cut burial–ritual site of Tomba Della Scacchiera in the north-western highlands of Sardinia, a spectacular array of painted imagery was discovered (Arosio et al. 2011). The Tomba Della Scacchiera or Chequered Tomb, so named for a unique blue-and-white checker design across the ceiling, comprises a fac¸ade and an entrance leading to a rock-cut passage and a massive chamber with three side cells beyond. The walls were painted with characteristic curvilinear and rectilinear motifs which are also found elsewhere in Neolithic burial–ritual monuments in central and western Mediterranean and north-western Europe. Additional to the geometric motifs was a series of stylistic bull heads carved along the main wall of the chamber. This recurrent theme appears to have been an important symbol across the western Mediterranean and the Iberian Peninsula at this time. The most striking element of the surviving rock art here is a set of seven interconnecting, large, vibrant, red spirals–very similar in style, size, and composition to carved examples found within burial–ritual monuments in Ireland, Scotland, and Wales (Figs. 5 and 6).

Key Issues and Current Debates

So far, I have briefly identified the geographic distribution of megalithic art, from the Mediterranean to Orkney (see Fig. 1). I now wish to discuss, albeit briefly, past and current ideas on this unique assemblage; clearly these symbols represent some form of visual communication system and were associated with ritualized death and burial rites within stone chambered monuments (usually passage graves). During the latter part of the twentieth century, much of the megalithic rock art had been recorded using traditional classifications and methods usually employed with cataloguing portable artifacts, usually by enthusiastic amateurs (Bradley et al. 2001: 494). From these rudimentary studies, researchers began to link together certain core areas of Europe, suggesting

Megalithic Art: A Visual Repertoire for the Dead, Fig. 6 The recording of the engraved spiral at Llanbedr, North Wales, image taken in 2012. (Image: author)

geographic associations that were bound by a recognized artistic tradition and monument building (Nash 2012).

With the application of AMS chronometric-dating techniques of minute fragments of organic material, archaeologists can now safely establish a potential route-map through Western Europe for the construction and use of burial monuments and the use of an artistic repertoire. However, questions arise concerning the relationship between monument and rock art, moreover the meaning each may have conveyed. The transmission of ideas through a set of recognized symbols may have occurred during the initial wave of monument construction, suggesting a contemporarity between art and monument. In the case of the reuse of stone work within several of the Brittany passage graves, it appears that the megalithic art tradition was already in place and, therefore, these symbols represented different spatial and temporal zones; this hypothesis can be suggested for Bryn Celli Ddu, a passage grave in Anglesey in North Wales. Here, excavation in the early twentieth century revealed a highly decorated stone lying over a central pit that may have once been part of a henge monument (Fig. 7). Later use of the site, at around 3000 BCE, includes the construction of the passage grave which appears to have used the foot print of the former henge. Interestingly, none of the walls inside the passage and chamber areas of this monument are engraved with megalithic art.

The concept of passage grave monuments acquiring megalithic art sometime after construction suggests two or more waves of elaboration to existing monuments. Certain passage graves located within the Gulf of Morbihan and the Bryn Celli Ddu demonstrate that megalithic art (in one form or another) was already in place but engraved on other types of monument. Based partly on the concept of reuse/recycling, one could also suggest that certain stones were chosen and engraved prior to construction. Alternatively, established monuments with along ancestral past could have, as part of their development, been engraved. I say this because in Ireland, of the 225 or so passage graves standing, only around 15% possess mega-lithic art (Waddell 2005: 57); similar ratios exist elsewhere in Atlantic Europe. Clearly, Neolithic communities made a choice of whether to incorporate megalithic art or not; could this choice have been merely a trend or a veering away from the old religion to a nonconformist tradition?

Looking Beyond the Motif

Megalithic art became a recognized pre historic tradition during the early part of the twentieth century, and since then a number of dedicated researchers have attempted to provide meaning to this enigmatic set of symbols. The general consensus is that it is a derivative of a much wider Schematic art tradition which may have its origins in the Mesolithic. Elizabeth Shee Twohig was the first researcher to collate and synthesize most of the then known European Neolithic sites that possessed

Megalithic Art: A Visual Repertoire for the Dead, Fig. 7 The Pattern Stone recovered from a central pit within a probable henge that originally stood under Bryn Celli Ddu, Anglesey, North Wales, British Isles. (After Lynch 1991) lines, wavy lines, and a spiral which he interpreted as mountains, the sea, and a celestial body – probably the sun or moon; the "scene" appeared to replicate the scape to the east of the monument (revealing a view of Snowdonia and the Menai Straits [a stretch of water between the North Wales main land and the island of Anglesey]) (Fig. 8)

megalithic art (1981). This monumental corpus of material has provided an essential starting point for research in later prehistoric rock art studies. During the next two decades, researchers such as Aubrey Burl, Richard Bradley, Paul Devereux, and Jeremy Dron field have gone some way to infuse meaning into what the various symbols might represent; for example, Bradley (2009) and Devereux (2009) introduced the reader to sensory components that are intangible and have not survived the archaeological record. In another ground breaking piece of research, Dronfield examined the significance of the passage component in Irish passage grave tombs (1996). He established that there was an association between the passage and engraved curvilinear motifs, in particular, concentric circles. He considered the idea that special people, such as shamans, would experience a tunnel experience which would be induced via altered states of consciousness as a means of accessing the supernatural world of the inner passage and chamber areas; the devices for this experience were the various curvilinear motifs that inhabited the tomb.

In a wider landscape sphere, megalithic motifs have been considered as landscape features (Nash 2012). Using the rock art from the passage grave of Barclodiad y Gawres in North Wales, Nash considered the design sequence on Stone 16, a large upright that appears to have delineated the space where the inner passage converges with the chamber. The panel design contained finely pecked multiple zig zag

Similarly, Kate Sharpe (2007) promoted the idea of a celestial body (represented by a complex

Megalithic Art: A Visual Repertoire for the Dead, Fig. 8 The design sequence on Stone 16 in Barclodiad y Gawres, Anglesey, North Wales, British Isles. (After Lynch 1991)

spiral motif) moving across the panel of Copt Howe, Langdale, in the uplands of Cumbria, northwest England to eventually set behind a series of lines that may represent the summit of a prominent peak within the Cumbria mountains (Fig. 9a–c).

In both examples, the spiral potentially represents a celestial body, but what of the concentric circle? Abreu (2012) has suggested that the concentric circle, one of the most common later prehistoric symbols within the Atlantic coastal fringe, is found exclusively near water on exposed rock out cropping (and occasionally on megalithic monuments), possibly representing the ripples that are created from dropping a stone into the water. This interesting and conceivable hypothesis is one of a number that require further systematic investigation.

Future Directions

Based on existing chronologies, survey coverage, and geographic scope, there is a probable association between monument, landscape, and megalithic rock art, what I have recently termed as *architecture, aspect, and art*, an intimate relationship between the rock art, the monument, and the landscape in which it stands (Nash 2013). Despite the large number of burial–ritual monuments in Western Europe, only a small number belonging to the passage grave tradition appear to be decorated. While there are differences in association, the evidence suggests that the repertoire of abstract motifs remains constant throughout the Mediterranean and Western European Neolithic core areas with certain motifs establishing distinct trends that create local and regional identity. However, in terms of universality, a recognized repertoire of motifs does extend along some 4,000 km of coastline; therefore, do they maintain the same grammar, meaning, and potency throughout this region of Europe?

It is conceivable that much of the artistic repertoire employed inside burial–ritual monuments during the Neolithic was later replicated on open-air panels, particularly those found in Galicia, northern Britain, and southern Scandinavia. This similar art form, also hidden in the upland landscapes of Western Europe, would have stood close to burial–ritual monuments such as barrows and round cairns that were constructed during the Bronze Age. Not surprisingly, this significant change in the location of (former) megalithic motifs occurs roughly in the same areas where megaliths were once active. However, the same question arises: does open-air rock art possess the same meaning as it did when originally engraved into a passage or chamber of a megalithic monument? If this were the case, the coastal fringes of the Mediterranean and Western Europe could boast a semiotic idiom that was in dynamic circulation for over 3,000 years and may have formed the foundations of a pictographic-based language, a visual communication system centered on death, burial, and ritual, as well as concealing ritual knowledge from nonelite members of the community.

Megalithic Art: A Visual Repertoire for the Dead, Fig. 9 (**a**–**c**).The trajectory of the setting sun (?) and how it was characterized in the rock art from Copt Howe, Cumbria, Northern England, British Isles. (After Sharpe 2007)

Megaw, Vincent

Gary T. Jackson
College of Humanities, Arts and Social Sciences, Flinders University, Adelaide, SA, Australia

Basic Biographical Information

John Vincent Stanley Megaw (Fig. 1) was born in Stanmore, Middlesex, in 1934. One of his uncles, A.H.S. (Peter) Megaw, was a distinguished Byzantinist, the last Director of Antiquities of the former British Colony of Cyprus, and a Director of the British School at Athens. Another uncle, Basil, studied archaeology at Cambridge and was Director and Librarian of the Manx Museum on the Isle of Man. In 1940 young Vincent Megaw's archaeological education began after he was evacuated to his grandparents' Belfast home, which was filled with ancient curiosities largely collected by his uncles. This interest led him to join the London Institute of Archaeology as a Member at the cost of five shillings a year at the age of 16 years.

In 1953 Vincent Megaw enrolled in an Honors M.A. in Prehistoric Archaeology at Edinburgh University, with Fine Art as a second subject. It was here that Professor Stuart Piggott suggested that he study early Celtic Art, which was to become a primary focus of Megaw's teaching and research career. In 1958 Thames and Hudson recruited him as an in-house editor, and the young Megaw found himself correcting the English of archaeological luminaries such as Sir Mortimer Wheeler, Max Mallowan, and Grahame Clark.

The year 1961 was a watershed year in Vincent Megaw's life. This was the year that he married Ruth Miller, then the youngest Third Secretary in the UK Foreign Office, who became

Megaw, Vincent, Fig. 1 Vincent and Ruth Megaw in 2001 at Flinders University on the occasion of the publication of the second edition of their book *Celtic Art from Its Beginnings to the Book of Kells*. (Credit: Multimedia Unit, Flinders University)

Megaw, Vincent, Fig. 2 Vincent Megaw with his son Jonathan Megaw and cat, Passang. Eden Hills, South Australia. October 2019

his close collaborator and coauthor in his various projects. Together, the Megaws have published extensively on European Iron Age art (e.g., Megaw and Megaw 1989, 1990) and soon established an international reputation as experts in this area.

Also in 1961, Vincent Megaw was appointed as Lecturer in European Iron Age Archaeology at the University of Sydney, Australia. He enrolled in a part-time external Ph.D. on "The Human Form in La Tene Art" at Edinburgh University that he did not complete. Megaw (2012: 551) recalls that Stuart Piggott commented that this was the first time that one of his postgraduate students had not completed his thesis but published the book instead (Megaw 1970).

In 1972 Vincent Megaw was appointed to the Chair of Archaeology at Leicester University, following in the steps of Charles Thomas. At Leicester University, he established an Honors B.A. in Archaeological Studies, which he complemented with a textbook (Megaw and Simpson 1979). In 1982 Vincent Megaw returned to Australia when he was first appointed to Flinders University in South Australia as a Lecturer in Visual Arts with a remit to introduce courses in prehistoric and ethnographic art. At Flinders University, he devised a new Bachelor of Archaeology degree within a Department of Visual Arts and Archaeology. In 1996 he was appointed to a Personal Chair in Visual Arts and Archaeology.

Professor Megaw's keen interest in music has manifested in various ways during his career. One of his subsidiary interests is music archaeology, and his first publication in *Antiquity* was on bone flutes (Megaw 1961). Also, while at Flinders University, he convened a series of weekly concerts and managed the Flinders University Chamber Ensemble.

Professor Megaw's achievements include an M.A., D.Litt. (Edinburgh); Fellow, Australian Academy of the Humanities; Fellow, Society of Antiquaries of London; Honorary Fellow of the Society of Antiquaries of Scotland; Korresp. Mitglied d. Deutschen Archäologischen Instituts; and Member, Institute for Archaeologists (UK). In 2004 he became a Member of the Order of Australia for service to archaeology and art history as an educator, researcher, and writer, particularly in the areas of European Iron Age art, contemporary Indigenous Australian art, and music archaeology.

In 2000 Professor Megaw and Ruth Megaw were appointed as Honorary Research Fellows in the Department of Archaeology at Glasgow University. Vincent Megaw retired and was appointed Emeritus Professor at Flinders University in December 2002. He continues his research and writing.

Major Accomplishments

Vincent Megaw had several successes very early in his career. From 1956 to1963, he joined Charles Thomas' long-running excavations at Gwithian in Cornwall. In 1958, Megaw discovered evidence of cross-plowing using an ard plough in the Bronze Age levels of the site. Previously, this feature has been known only from Scandinavia and the Netherlands (Nowakowski et al. 2007).

While at Sydney University during the 1960s, Megaw conducted pioneering fieldwork on the Indigenous archaeology in the Sydney region. Colleagues at this time included Rhys Jones and Betty Meehan, who was one of his students for a time. Megaw's research was undertaken against the opposition of both J.R.B. Stewart, the Foundation Edwin Cuthbert Hall Professor of Near Eastern Archaeology, and his successor as Professor of Archaeology, the Classical archaeologist, Alexander Cambitoglou, who banned university time or money being spent on the archaeology of Australia. Megaw confronted this ban by excavating at weekends and during vacations (Megaw 2012). His work during this period included significant excavations on the shores of Botany Bay near the location of James Cook's landing in 1770 (Megaw 1969).

During the 1970s and 1980s, Vincent Megaw was one of a very few scholars who held that the Indigenous Arts of Australia should be understood as art, rather than as ethnographic objects (Megaw 1982). Intrigued by the art of the Western Desert in Central Australia, he collected early acrylic paintings made by these communities in the years before these paintings were accepted as art. On behalf of the Flinders University Art Museum, Megaw established a significant collection of Western Desert paintings. He also acted to promote the artists more widely. Supported by the Aboriginal Arts Board of the Australia Council, he initiated a series of short-term residencies for Indigenous artists. Later, he initiated an important traveling exhibition, *The Heritage of Namatjira*, on the work of watercolor artists from Central Australia. This was accompanied by a pioneering collection of essays (Hardy et al. 1992) that provided scholarly and cultural insights into this body of work.

The European facets of Megaw's research also flourished, and his firsthand experience in Europe continued as it has to the present. Between 1978 and 1981, Vincent returned to Austria and the Dürrnberg bei Hallein (the ancient salt-mining center south of Salzburg) as part of a Leicester rescue project in advance of the construction of an all-weather road from Hallein to Berchtesgaden, renowned as the former location of Hitler's summer villa. Vincent and Ruth Megaw's major survey of early Celtic art (Megaw and Megaw 1989, also forthcoming) was followed by a monograph on the Basse-Yutz find, now one of the major treasures of the British Museum (Megaw and Megaw 1990) as well as many later publications including reviews dealing with the ancient Celts – in whom he still believes

in spite of much controversy (Megaw 2007, 2010, 2013). Professor Megaw's fine scholarly skills are captured in Rudolf Echt's assessment:

Megaw… is at his best in tracing formal relationships between individual works, in recognizing formal dependences and influences (Echt 1999: 251, cited in Megaw 2012: 555).

In the early 1990s, Megaw's track record established a basis for several large grants from the Australian Research Council. This funding allowed him and Ruth Megaw to examine various facets of Celtic art in depth (Megaw and Megaw 1996, 1997) and to conduct excavations that shed new light on Dürrnberg's long mining history (Megaw 1990; Megaw et al. 2000).

In retirement, Megaw continued to be active, giving occasional lectures until well into his mid-80s (Fig. 3) and working on the completion of the magnum opus he conceived with Ruth Megaw, a supplement to the bible on the subject, Jacobstahl's (1944) *Early Celtic Art* (see Megaw and Megaw forthcoming).

The scholarly career of Professor John Vincent Stanley Megaw has spanned two continents and five decades. During this time he initiated significant academic programs at two universities, established a major collection of Australian Aboriginal art, and conducted internationally leading research. Most particularly, with his wife and colleague, Ruth Megaw, he has revolutionized understandings of Celtic art in Europe and made a major and early contribution to the recognition and scholarly analysis of Indigenous art in Australia. In 2012 he responded to the invitation of Martin Carver, then Editor of *Antiquity*, to write a personal survey of his life. It stands as a characteristically lively self-generated critique of the man and his work – so far. In 2013, Flinders University established the Ruth and Vincent Megaw Annual Lecture,

Megaw, Vincent, Fig. 3 Vincent Megaw teaching in Claire Smith's Archaeology of Art topic, Flinders University, South Australia. June 2019

in recognition of a lifetime of joint service to archaeology. Sadly, Ruth Megaw died in July, 2013. In 2014, a few days after his 80th birthday, he was presented with a *festschrift* honoring his work on Celtic art (Gosden et al. 2014).

Meggers, Betty Jane

Cristiana Barreto
Museu de Arqueologia e Etnologia, Universidade de São Paulo, São Paulo, Brazil

Basic Biographical Information

Betty Jane Meggers (December 5, 1921 – July 2, 2012) was one of the most influential figures in the history of South American archaeology. She conducted research in the Amazon area, with her husband Clifford Evans, for almost half a century, starting as a graduate student in 1948.

Betty Meggers was born in Washington, DC, to Dr. William Frederick Meggers and Edith R. Meggers. Her father was an internationally recognized spectroscopist and an archaeology enthusiast. At the age of 16 Betty Meggers became a volunteer at the Smithsonian Institution and helped to reconstruct pots excavated from Pueblo Bonito, an Anasazi village in New Mexico.

In 1943, Betty Meggers graduated from the University of Pennsylvania with a Bachelor's degree. A year later she was awarded a Master's degree from the University of Michigan. At the University of Michigan, Meggers was introduced

to ceramics from the Marajo Island, at the mouth of the Amazon, and published her first scientific article on Marajo pottery in 1945. After obtaining her Master's Degree, she attended Columbia University to finish her Ph.D. At Columbia she was strongly influenced by anthropologist Julian Steward and his new "cultural ecology" approach, but also was enthusiastic about Leslie White's theories of socio-cultural evolution. She also met Clifford Evans at Columbia, a fellow graduate student. They married in 1946, and set off for fieldwork in Marajó about a year later.

During her lifetime Betty Meggers received many awards and honors in recognition of her long and consistent scientific contribution to knowledge of the South American past. She passed away in 2012, at the age of 90, after serving 68 years as research associate with the Department of Anthropology at the National Museum of Natural History, Smithsonian Institution.

Major Accomplishments

Betty Meggers' accomplishments encompass both research and training. Based at the Smithsonian Institution in Washington, she had an active role in the training of South-American archaeologists as well as the development of long-term archaeological research programs in countries such as Brazil, Guyana, Ecuador, Peru, Venezuela and Chile. Her theories about the origins and development of South American Indigenous cultures have dominated the field of Amazonian archaeology for decades and remain at the center of debates about the socio-cultural history of the region.

In 1948 Betty Meggers wrote one of the few pieces about archaeology published in the *Handbook of South American Indians* edited by Steward (Meggers 1948). Her article on the archaeology of the Amazon basin formed the basis for the theoretical argument developed in her much debated article on the "Environmental Limitation on the Development of Culture" published a few years later (Meggers 1954). Meggers believed that culturally complex societies could not have evolved in the Amazon due to supposed lack of protein and poverty of soils that had prevented intensive agriculture and population growth. Therefore, any sign of social complexity in the Amazon basin, as was implied by the elaborate Marajoara ceramics, had to be interpreted as immigrations of Andean or Caribbean groups, who were fatally doomed to degeneration and decay in a tropical environment. Her theories had a definite impact in characterizing South American tropical lowlands as a marginal area of social development, and reinforced the concept of cultural degeneration within the already biased colonialist Indigenous history of the region. These ideas have been questioned both by subsequent research at the mouth of the Amazon (Roosevelt 1991; Schaan 2012) and the more recent literature on the decolonization of archaeology in Brazil (Noelli and Ferreira 2007).

It is widely recognized that Betty Meggers' focus on cultural ecology and adaptation was highly innovative for her time. Moreover, throughout her career, her research and that of her associates produced enormous amounts of data on different kinds of resource distribution and variability in the Amazon, as well as data on the ecological history of the region, such as climatic changes during the Pleistocene-Holocene transition, the early human occupation of the region, and the evolution of forest environments.

In addition, Meggers is known for her controversial assertion of a trans-Pacific cultural connection between East Asia and South America long ago based on similarities of pottery fragments found in Japan and Ecuador. She contended that Japanese Middle Jomon pottery was similar to ceramics from the Valdivia site in Ecuador – both dating between 2000 and 3000 B.C. To support her argument Meggers stated that plants, pathogens, and parasites of Japanese origin are found among Andean populations.

Betty Meggers also made an important contribution in terms of methodology. In collaboration with Clifford Evans, she developed systematic procedures for both site surveying and ceramic analysis and seriation, the latter building on James A. Ford's typological approach, classifying ceramic complexes into phases, traditions and horizons. These were passed on to a great number

of South American scholars through courses, seminars and collaborative research programs. In Brazil, the PRONAPA (Programa Nacional de Pesquisas Arqueológicas, 1964–1970) coordinated by Meggers and Evans, had a profound impact on both the generation of data and the establishment of a chronological framework for the distribution of cultural archaeological traditions, phases and sub-phases, throughout the national territory.

Megger's legacy continues to be imparted through research associates in South America who carried her influence to new generations of archaeologists. Important figures here are Mario Simões, Eurico Miller and Ondemar Dias in Brazil, Emilio Estrada in Equador, José. M. Cruxent in Venezuela, Mario Sanoja and Iraide Vargas in Colombia.

Betty Meggers wrote nearly two hundred articles, book reviews, translations, and books. She published in many leading scientific journals including *American Anthropologist, American Antiquity, Americas, and National Geographic*. Results from her Ph.D. dissertation appeared in a seminal 1957 publication co-authored by Evans that remains a main reference in the archaeology of the mouth of the Amazon till this day (Meggers 1957). Her most cited books are *Amazonia: Man and Culture in a Counterfeit Paradise* (Meggers 1971) and *Prehistoric America: An Ecological Perspective* (Meggers 1972).

Megiddo and the Megiddo Expedition

Eric H. Cline
Department of Classical and Near Eastern Languages and Civilizations, The George Washington University, Washington, DC, USA

The site of Megiddo (biblical Armageddon) has been under excavation, on and off, for more than a century. Four different groups have excavated at the mound to date, including a German-sponsored team led by Gottlieb Schumacher from 1903 to1905, Americans from the Oriental Institute of the University of Chicago from 1925 to1939, and Israelis under Yigael Yadin for several brief seasons in the 1960s and 1970s. The international Megiddo Expedition, led by Tel Aviv University, is the most recent of these four, beginning with an initial foray in 1992 and then launching officially in 1994. This brief entry will focus on this most recent expedition.

History of the Megiddo Expedition

Excavating every other year, in even-numbered summers, the Megiddo Expedition has been

ongoing for more than two decades so far. It is the longest-running archaeological project to take place at the site.

A triumvirate of co-directors led the project for the first decade (1994–2004): Israel Finkelstein (Tel Aviv University), David Ussishkin (Tel Aviv University), and Baruch Halpern (Pennsylvania State University). A variety of universities participated in an International Consortium, sending students and faculty each season; this was led by Penn State as senior member, in conjunction with Tel Aviv University.

Following the 2004 season, Baruch Halpern and Penn State formally left the project. George Washington University (GWU) replaced Penn State as the senior consortium member, and Eric H. Cline was appointed associate director (USA), while Finkelstein and Ussishkin continued as co-directors.

David Ussishkin retired from the project after the 2010 season. Cline was promoted to co-director and served in that capacity with Finkelstein for the 2012 and 2014 seasons, before retiring in turn; at that point, GWU remained a member of the Consortium but relinquished its position as senior member. Mario A.S. Martin and Matthew J. Adams served with Finkelstein as co-directors for the 2016 and 2018 seasons.

Primary Areas of Excavation

Area F (1994–1996): Located on the lower part of the mound, close to the current-day museum/gift shop/restaurant, Area F provided evidence for probable Middle Bronze (MB) fortifications, in the form of a glacis, as well as sparse remains from later periods, including the Late Bronze (LB) period and the Iron Age (IA). One notable find included a Neo-Assyrian faience vessel, found in a grave.

Area H (1994–2018): Positioned on the edge of the upper portion of the mound, in an area where the University of Chicago had uncovered two Neo-Assyrian palaces from the eighth century BCE, the initial squares opened up in 1994 and in 1996 had to be closed down when the Israel Antiquity Authority (IAA) forbade excavations to dig too close to the edge. Subsequently, a step-trench was begun on the slope next to Chicago's excavations that had previously revealed the LB palace and its famous ivories. Beginning in Neo-Assyrian levels, the excavations have now reached the period of the Middle Bronze Age, revealing several different destructions along the way, which yielded good material for radiocarbon dating.

Area J (1994–2012): Located in Chicago's Area BB and overlapping with part of Schumacher's Great Trench, Area J has primarily yielded remains from the Early Bronze (EB) period. These include a huge structure identified as a temple, located in the region of the iconic circular altar uncovered by Chicago. This may be the largest such temple yet found in the Levant dating to this period. Egyptian influence may be detected in some phases of the building, which also seems to have suffered damage from earthquakes at one or more times in its history.

Area K (1996–2018): Situated on the southeastern side of the upper mound, Area K follows a similar sequence to Area H, with excavations beginning in Neo-Assyrian layers and continuing down into Middle Bronze levels. The area seems to have housed domestic structures and possible workshops for much of its history, though a number of tombs and burials have been found as well. In addition, a wide mudbrick wall dating to the Middle Bronze Age was uncovered, which is likely to have formed part of the fortification of the mound during the second millennium BCE.

Area L (1998–2007): Located at the northern part of the mound, Area L is in a region where the Chicago excavators had previously found the remains of buildings that they identified as stables and where Yadin excavated portions of Palace 6000. Investigations in this area exposed and clarified the entire plan of Palace 6000, demonstrating conclusively that it did not date to the time of Solomon, as Yadin had suggested. Directly above, and reusing stones from the palace, a building containing what appear to be five tripartite rows of probable stables was fully revealed; again, this does not belong to the time of Solomon, as the Chicago excavators had believed, but is most likely from a time at least a century later.

Area M (2000–2006): In an area next to and including part of Schumacher's Great Trench, located in the middle of the uppermost part of the mound, Area M yielded large amounts of fallen mudbrick debris from various buildings located in the region of Schumacher's Mittelburg.

Area Q (2008–2016): On the southern edge of the upper mound, looking across to the current prison located at the crossroads of Megiddo Junction, Area Q is located in an area first investigated by the Chicago archaeologists in 1925 and 1926. It has yielded evidence of occupation primarily from the Iron Age, including a large pillared building and at least one destruction level. Remains of spent cartridge cases found in the uppermost levels tell the tale of a battle fought for control of the mound in 1948.

Area S (2014–2018): Situated just inside the Late Bronze Age gate, in the area where the Chicago excavators excavated down through the LB palace, Area S revealed remains from the Middle Bronze Age. These included possible evidence for a gate system that once stood in the area during this period.

Publications

In addition to numerous co-authored articles that have appeared in a variety of peer-reviewed scholarly journals, the Megiddo Expedition has published its preliminary results after every three seasons of excavation. Thus, *Megiddo III* (2000) covers the 1992–1996 seasons, *Megiddo IV* (2006) the 1998–2002 seasons, *Megiddo V* (2013) the 2004–2008 seasons, and *Megiddo VI* (forthcoming) the 2010–2014 seasons.

Mellaart, James

Jana Rogasch
Jana Anvari, Institut für Ur- und Frühgeschichte, Universität zu Köln, Köln, Germany

Basic Biographical Information

James "Jimmy" Mellaart was born on 14 November 1925 in London to Dutch parents with whom he returned to the Netherlands in 1930. It was in the Netherlands that he first developed a fascination for antiquity in school, particularly while working at the National Museum of Antiquities at Leiden during the Nazi occupation.

In 1947, Mellaart returned to London to study history and Egyptology at University College London. In his formative years around the time of his graduation in 1951, he took part in excavations in different parts of the Near East, including Jericho and Fikirtepe in Turkey, where he met his future wife Arlette. Soon after he graduated, he started working with the British Institute of Archaeology at Ankara (BIAA), where he was appointed as Assistant Director in 1959. Archaeologists at the BIAA, which was founded in 1948, were working in central Anatolia, exploring a part of the Near East that had previously received little archaeological attention. Mellaart took an active part in this pioneering work during numerous surveys on foot and through the excavation of sites he had identified.

He recognized the potential of the Late Chalcolithic/Bronze Age site of Beycesultan, and directed excavations at this site from 1954 to 1959 together with the experienced director of BIAA, Seton Lloyd. Soon, two more large-scale excavations followed at Neolithic/Early Chalcolithic Hacılar in the Lake Region from

1957 to 1960 and at Neolithic Çatalhöyük from 1961 to 1965.

In addition to his fieldwork in Turkey, Mellaart taught archaeology at Ankara and Istanbul. After he had to leave Turkey in 1965 (see below), he was appointed to a newly created lectureship in Anatolian archaeology at University College London where he taught from 1965 until his retirement in 1991.

James Mellaart died on 29 July 2012 in London.

Major Accomplishments

The work of James Mellaart and his colleagues at the BIAA placed Neolithic to Early Bronze Age central Anatolia on the radar of archaeologists. Prior to that, this area of research was somewhat underdeveloped compared to the significant processes and events known from the Levant and Mesopotamia. This view changed dramatically when the remarkable findings of Hacılar and Çatalhöyük became known to the archaeological community and the public (Redman 1972; Mellink 1973). Çatalhöyük was declared a UNESCO World Cultural Heritage in 2012 shortly before Mellaart's death.

Jimmy Mellaart is described by colleagues and student as talented, knowledgeable, spirited, inspiring, charming, and very able to present his data and thoughts in ways that fascinated archaeologists and the public alike. He had an independent mind and the instinct to find sites that would substantially enhance knowledge about Anatolian prehistory.

Mellaart's publications (e.g., 1965, 1967, 1970, 1975) are widely read. Many of his interpretations have been revoked as archaeological knowledge and fashions of thought progressed during the last decades (e.g., Farid 2008; Rosenstock 2010). These new publications not only show how far the knowledge about prehistoric central Anatolia has advanced since the 1960s, however, but also demonstrate once more the importance of Mellaart's pioneering excavations, and of his progressive interpretations that triggered scholarly discussions (e.g., Todd 1979).

During Mellaart's work as an archaeologist, there are mooted instances of imagination and facts becoming confused. Several reviewers of his early work (e.g., Whallon 1968; Redman 1972) criticized this as a general tendency in his excavation publications. A prominent example is the Dorak affair in 1965, during which Mellaart claimed to have inspected a rich collection of Bonze Age artifacts in 1958 at a young woman's house in Izmir, but neither the house, nor the woman, nor the artifacts were ever found. This inconsistent story made Turkish authorities suspect Mellaart of being involved in smuggling antiquities, together with the discovery that artifacts excavated in Hacılar and Çatalhöyük disappeared from depots and made their way to the antiquity market. In 1965, this culminated in Mellaart being banned from Turkey and from ever excavating there again; he was only permitted a very brief visit to the renewed excavations at Çatalhöyük in 2005.

Another controversy developed around accounts of wall paintings supposedly excavated at Çatalhöyük, published by Mellaart in the 1980s. The existence of these paintings was doubted by many since their style, content, and state of preservation were much more spectacular than that of the paintings published in the 1960s, and because no original photos or drawings of the paintings exist (Mellaart 1984, 1985, 1989, and later comments and replies to critics; reviewed among others by Lamberg-Karlovsky 1992; Mallett 1990, 1992).

While such accounts can be disconcerting for most of colleagues, such ambiguities do not diminish the fact that James Mellaart's "contribution to the unfolding of the Anatolian Neolithic and Chalcolithic periods was enormous and fundamental" (Watkins 2012).

Meroë

Anna Lucille Boozer
Department of History, Baruch College and The Anthropology Program, The Graduate Center, City University of New York, New York, NY, USA

Introduction

Meroë (Meroitic: Bedewe/Medewe) is located near modern Begarawiya (Northern Province, Sudan) at 16.54 N latitude and 33.44 E longitude, ca.120 km north of modern Khartoum. Meroë was one of the most significant administrative, religious, and artistic centers of the ancient kingdom of Kush between approximately the seventh century BCE and the fourth century CE, although these dates are far from certain. It seems that Meroë was a substantial town under Nubia's Napatan rulers (ca. 760–270 BCE) and rose in status to become the capital of the Meroitic Kingdom (ca. 270 BCE-350 CE). Although we have archaeological remains of considerable but uncertain time depth, the earliest-known inscriptional reference dates to the Napatan ruler Iriki-Amanote (ca. 431–405 BCE). The site may have been used as a residence for members of the royal family for some time, but Arkamani was the first known ruler to be buried there (Beg. S 6) (ca. 270–260 BCE). From this point onward, Meroë remained the royal burial ground until the end of the Meroitic State. Meroë is regarded as one of the oldest and most significant urban settlements in Africa outside of Egypt.

Definition

Meroë is situated on the east bank of the Nile, which provided the city with a major commercial and strategic route. This placement linked Nubia to Egypt and the Mediterranean, the Gezira (the region between the Blue and White Niles), to Axum (Ethiopia), and to the Red Sea. The environment surrounding Meroë has significant

rainfall and possessed substantial agricultural and grazing lands. Other natural resources include varieties of sandstone for constructing monumental structures, iron ore for the smelting industry, and clays for ceramic production.

Meroë city occupied a large area that was approximately 2.6 square km. The dominant component of the western portion is an enclosure known as the "Royal City." Based upon our current understanding of Meroë, the Royal City appears to be a walled precinct that is roughly rectangular in shape, measuring approximately 275 × 137 m. A labyrinth of mixed-usage buildings reside within these walls, many of which are monumental in size and ornamentation. Most of the buildings are composed of mud brick with exterior faces of baked brick and a few buildings built of stone. The buildings in the Royal City were repaired and rebuilt innumerable times, which creates a very complex tell formation of occupational history (Hinkel 2002). As a result, the original ground topography is difficult to interpret (Adams 1984 [1977]), and the phasing of the settlement is understood poorly. Large, square buildings, nearly identical in size, are located near the center of the walled enclosure and are believed to be palaces. Other buildings have been interpreted as storage magazines, audience chambers, and domestic quarters for the palace staff.

Since the advent of formal excavation, the buildings in the Royal City have been designated using the system M xxx. M stands for Meroë, while the numbers designate specific structures within the Royal City. The surrounding cemeteries use a different numbering system: Beg. N/S/W x. "Beg." stands for Begarawiya, the village near Meroë. The letters designate the cemetery – North, South, or West – and the numbers denote the specific tomb (Reisner 1923a, b; Dunham 1963).

Temple of Amun (M 260) adjoins the enclosure on the eastern side and is the dominant temple. Amun was an Egyptian god adopted and worshipped in a distinctive manner by Nubians. The Temple of Amun is the southern equivalent of the great temple of Amun at Jebel Barkal. The Temple of Amun is large (137 m long) and included a colonnaded court, columned halls, and a sanctuary on top of a platform. A processional route led from the Temple of Amun to a so-called Temple of the Sun (M 250) outside of the city. The Temple of the Sun was an enclosed area with a single-chambered cult building surrounded by a colonnade and standing on a platform (Hinkel 2001). Additional temples line a processional street through Meroë in this vicinity. There was also a small prostyle temple to Victory (M 292), in front of which was found the famous bronze head of Augustus, which the Meroites may have looted from Egypt in 23 BCE. The Royal Ontario Museum, directed by Krzysztof A. Grzymski, has re-excavated the temple precinct and provided new understandings about the temple area (1999–2009) (Grzymski 2003) (Fig. 1).

One of the most distinctive buildings of the site is the so-called Royal Bath, which is a Roman style nymphaeum complemented with Hellenistic style sculpture. The Humboldt University of Berlin continued excavations at the Royal Bath at Meroë from 1991. The German Archaeological

Meroë, Fig. 1 Faience object with suspension ring (INV 518); drawing by Sarah Lambert-Gates, Courtesy of the Meroe Archival Project

Institute (DAI) has been excavating this area from 1999–2000 to the present day. Simone Wolf and Hans-Ulrich Onasch direct this research. The current DAI project investigates the chronology and the building phases, the cultural influence from the Mediterranean, the hydrotechnical installations, and the function of the building complex in the context of the Royal Court and the City of Meroë (Wolf 2015). For the protection of the remains, a new shelter building, including a small exhibition to inform visitors, is intended.

Extensive, superimposed residential and industrial zones were located to the east and northeast of the Royal City. The houses are poorly understood as none of them were excavated in their entirety, and they were superimposed on top of one another (Shinnie and Bradley 1980). The Meroë Archival Project (MAP) team, directed by Anna Lucille Boozer, is re-examining the Shinnie material excavated from these structures. The ceramic assemblage includes a distinctive white-fabric ware made from locally sourced kaolin. Other ceramics include handmade black wares and a wheel-made brown ware, which seems to have been common to the domestic areas, as well as imported fabrics. Additional material comprises handmade figurines (predominately of quadrupeds), terra-cottas, weaving implements, weights and measures, jar seals, stamps, beads, lip/ear/nose plugs, metals, and numerous other objects relating to the social, economic, religious, and material life of ancient Meroë.

Slag heaps, thought to be from iron smelting, are located at the eastern edge of the city, marking the craft quarter. A UCL Qatar project, directed by Jane Humphris, is currently working in this area of the city. This project will expand over the coming years to include a number of additional iron production locations and to consider in more detail further pyrotechnologies. The multidisciplinary approach to ancient technologies, including mapping and modelling, dating, archaeobotany, geophysics, and geochemistry, alongside the exhaustive excavation sampling methodologies and laboratory analysis of archaeometallurgical and associated archaeological samples, will ensure a growing and holistic corpus of data is generated from this project. The results, spanning over 1000 years of technological history before, during, and after the Kingdom of Kush reached its zenith, will provide an understanding of the role and impact of technologies and technologists during this key period of time (Humphris 2014; Humphris and Rehren 2014). The UCL Qatar team is also collaborating with the MAP team to re-examine slag, crucibles, and iron objects that were recovered during the Shinnie excavations at Meroë.

Farther to the north and east are spacious burial grounds, including a field of pyramids belonging to the relatives of rulers (Fig. 2). Immediately to the east of the city are three discrete cemeteries, which provide an enormous source of information about this poorly understood empire. The northernmost of these cemeteries dates to ca. 100 BCE–200 CE. The other two cemeteries appear to have been active later. Most graves were marked with a mound of sand or gravel and appear to be those of the elite.

The pyramids of the kings and *kandakes* (ruling queens) are located still farther to the east and are arranged in a triangle. The western cemetery (among this triangle) included pyramid tombs of lesser royals. The northern and southern (among this triangle) include nearly all of the known rulers of Meroë after Arkamani. The pyramids were built of stone masonry, and the later phased ones were built of brick and rubble. These pyramids differed from the Egyptian pyramids; they were steeper, often had an attached chapel, and it seems that those belonging to the kings had a pylon (a double-towered gateway inherited from Egypt). Chapels had scenes and texts, which often repeated between the various tombs. A hoard of golden jewelry was supposedly found from these pyramids. This jewelry shows connections to Egypt and the Mediterranean (Priese 1992). There are other graves distributed among these pyramids in the south and the east cemeteries: mastabas (Arabic for "bench," describing the structure shape) and mounds. These graves appear to have been for queens, princes, and the elite.

Meroë had connections to the Roman Empire since Rome first occupied Egypt, although the

Meroë, Fig. 2 Pyramids of Meroë – Northern Cemetery; Ron Van Oers, photographer (CC-BY)

nature of these connections is contested (Yellin 2015b). It seems that Cornelius Gallus, the first prefect of Egypt, established the Egyptian border at the First Cataract in about 29 BCE. Subsequently, this border was pushed south by 70 miles to Hiera Sycaminos (Maharraqa) to include the Dodekaschoinos, a region of much-disputed control for this and the Ptolemaic era (Kirwan 1977). During the prefecture of Gaius Petronius (25–21 BCE), the Meroites attacked Syene, Elephantine, and Philae at the First Cataract. They were taking advantage of the transfer of troops from this area to Arabia Felix for Aelius Gallus' campaign there (Strabo XVII, 53–4). This attack is thought to be the one which resulted in Augustus' statue head being placed beneath the threshold of one of the temples at Meroë, which is often known as the Augustus Temple (M 292). During the first three centuries CE, the relationship between Rome and Meroë became peaceful. The movement of trade goods between Meroë and the Roman Empire (and particularly Roman Egypt) seems to suggest positive trade relationships ensued, as evinced by elite Roman Mediterranean goods found at Meroë, namely, lamps, glassware, beads, and adornment. Future work on material culture may provide more information on the nature of these exchanges.

Axum (along with some incursions by the Noba) has often been credited with destroying Meroe toward the middle of the fourth century CE (Kirwan 1977; Littmann 1938; Shinnie 1967). The archaeological evidence for Axumite destruction levels at Meroë is minimal (Bradley 1984).

Additional connections with other areas in Africa are certain, but further study of the material culture, archaeobotanicals, and faunal remains is required to identify specific locales with greater confidence.

Historical Background

Herodotus and other ancient writers mentioned Meroë, but little was known about it until the age of European exploration (Boozer 2017). The Scottish traveler James Bruce (1730–1794) first tentatively identified Meroë in 1772 on the basis of the Temple of Amun (M 260–280) (Bruce 1790). Bruce provided the first modern description of ancient Meroë:

> We saw here heaps of broken pedestals. . .pieces of obelisk, likewise, with hieroglyphs, almost totally obliterated. The Arabs told us these ruins were very extensive, and that many pieces of statues, of both men and animals, had been dug up there. . .It is impossible to avoid risking a guess that this is the ancient city of Meroë. (Bruce 1790)

Bruce does not mention the pyramids of Meroë, which have been the focal point of most antiquarian and modern-day interest at Meroë. Subsequent explorers, such as Frédéric Cailliaud (visited 1821), Linant de Bellefonds (visited 1821), and Karl Richard Lepsius (visited 1842–1845), included Meroë on their itineraries and described these pyramids (Cailliaud 1972 [1826–1827]; de Bellefonds 1958). Cailliaud, Linant, and Lepsius produced the first accurate drawings and measurements of the pyramids at Meroë. Lepsius was the first to archaeologically investigate a Meroitic pyramid (Lepsius 1849). These three missions provided the first scientific grounding for research upon Meroë.

Giuseppe Ferlini (lived 1800–1870) was one of the most notorious historical figures associated with Meroë because he hunted for treasure in the pyramids using destructive techniques (Priese 1992). Ferlini's quest was initially unsuccessful, but he eventually found jewelry in one (Beg. N. 6 of queen Amanisakheto). Ferlini hired four workers from neighboring villages and ordered them to dismantle the pyramid from the top down. Ferlini claimed that spectacular finds were located in chambers within the pyramid, along with some equipment used by the pyramid builders. According to a subsequent investigation by Hinkel, Ferlini likely opened the burial chamber within the pyramid and found the treasure there. Berlin acquired the majority of Ferlini's finds at the request of Lepsius (Priese 1992). Ferlini's discovery of treasure has drawn increased attention to the archaeology of Meroë by both archaeologists and looters. These looters appear to have been both Europeans and locals, as indicated by some of Lepsius' records (Lepsius 1852).

Sir Ernest Alfred Thompson Wallis Budge (lived 1857–1934), an English Egyptologist based at the British Museum, collected antiquities from Meroë for the British Museum. Troops furnished by Sir Reginal Wingate (lived 1861–1953), governor-general of Sudan (in office 1899–1916), made paths to and between the pyramids and sank shafts into the site. Little is known of the results of these explorations, although more might be learned from objects in the National Museum in Khartoum that may derive from this work and his personal papers preserved in the British Museum.

John Garstang (1910–1914), a professor of archaeology at the University of Liverpool (1907–1941), carried out the first formal excavations at Meroë. During Garstang's excavations (1910–1914), Meroë was positively identified by name. This identification was made in 1910 on the basis of the Amun Temple walls that he exposed and compared to descriptions of them by ancient writers. The mention of the city of *Mer* (?) in a hieroglyphic text of a stela of King Aspelta (late seventh–early sixth century BCE) found in fragments at Temple M 250 appeared to definitively corroborate this identification (Török 1997). This inscription fragment was not published by Garstang and was lost after the excavations were interrupted in 1914 (Török 1997). Garstang later attempted to connect the building periods of Meroë to known historical events. Garstang's work emphasized the importance of Egyptian and Hellenistic influences and imports upon Meroë. The First World War interrupted Garstang's fieldwork, and the results were not published in final form until László Török's multivolume publication in 1997.

George Reisner (1867–1942) was an American archaeologist who excavated Meroë's royal cemeteries located east of the city (1920–1923). Although Reisner did not publish his research

during his lifetime, his assistant, Dows Dunham (1890–1984), used his contextual descriptions to produce comprehensive reports (Dunham 1957, 1963). Subsequent scholars have used these reports to interpret the religious and mortuary practices of Meroë (e.g. Yellin 2012; 2015a).

The pyramids of Meroë were also subject to substantial restoration work by Friedrich W. Hinkel. This work has provided a new knowledge of the architecture of the pyramids and the method of their construction (Hinkel 1986, 2000).

The most sustained excavations in Meroë city were directed by Peter Lewis Shinnie (1915–2007) (Figs. 3 and 4). Shinnie excavated at Meroë (1965–1984, intermittent) as the director of a joint expedition of the Universities of Calgary and Khartoum (as the expedition was entitled in its final form) (Shinnie and Anderson 2004; Shinnie and Bradley 1980). Shinnie's excavations were the first to expose domestic houses, industrial areas, and components of the urban layout in addition to exploring the site's many temples.

The Meroë Archival Project (MAP), directed by Anna Lucille Boozer, re-examines the previously excavated material from Meroë. Among the objects examined thus far are decorative tiles, plaques, and medallions, which were probably inlayed in the floors and walls of the Temple of Amun as well as the smaller temples and shrines (Fig. 1). There are also numerous plaques and objects in the round provided with suspension rings, which were possibly hung from the ceiling, or from some kind of temple furniture. Some of these objects represent small shrines, feathers, and crowns. This analysis will hopefully shed light on diachronic change as well as the furnishings of Meroitic temples.

Key Issues/Current Debates

Due to the history of looting and nonscientific excavation at Meroë, many basic questions about the site remain unanswered. The contours of Meroë's occupational history remain uncertain despite more than a century of excavation. Current expeditions to Meroë are attempting to resolve outstanding questions relating to four main areas: iron production, the so-called Royal Baths, the Amun Temple, and the material culture.

UCL Qatar has documented and excavated the remains of extensive iron industries from key locations within the Meroitic landscape. They have demonstrated that the scale and the technological approach to iron working by Meroites situate it as a key industry. This research corroborates century-old suggestions about the significance of iron working at Meroë but is still in early

Meroë, Fig. 3 Peter Shinnie's excavation team at Meroe in 1975. The crew shown here is made up of students from the University of Calgary; Sam Gerszonowitz, photographer (CC-BY)

Meroë, Fig. 4 Peter Shinnie excavating in the 1970s; Janice Yellin, photographer (CC-BY)

stages of research. For example, the role of iron working in the rise, dominance, and collapse of the Kingdom of Kush is still unknown (Humphris and Rehren 2014).

The Royal Baths and the Temple of Amun have been explored for over a century. Like the site itself, these two loci remain poorly understood. The re-excavation of these two areas, by a German and a Sudanese team, respectively, promises to reveal more information about these structures as well as Meroë more generally. Excavations in the Royal Baths area have revealed water management systems, elaborate material culture, and potential garden features (Wolf 2015).

The material culture from Meroë was not published to modern standards or interpreted within their find spots. Ongoing re-examinations of this material inform interpretations of production, religion, and other social practices. For example, the many weaving implements found within domestic contexts inform interpretations of household production. Meanwhile, numerous fragments of faience tiles, objects in the round, and miniature shrines suggest complex religious practices unlike those in Egypt. Although it should be assumed that Meroites had their own approach to religion, there have been insufficient studies of how these approaches manifested themselves through portable material culture.

International Perspectives

British and European scholars have dominated current perspectives on Meroë. This Eurocentric interest has not been without issues; the excavations have not always been scientific; and all of them experienced significant time lags between excavation and final publication. These two problems have hindered more thorough archaeological interpretations of both the site and its material culture.

Sudanese archaeologists began to be included as research partners beginning with Shinnie's excavations; he trained a generation of Sudanese archaeologists at the site. Many of his former students are current faculty at the University of Khartoum, which maintains its permit for the site and conducts its own excavations at Meroë today.

Present-day international missions include Sudanese experts alongside international ones. Additional intertwining between international and local archaeologists is desirable for strengthening research outputs and community engagement.

The inscription of Meroë, as part of the Archaeological Sites of the Island of Meroë, as a UNESCO World Heritage Site in 2011 has brought renewed inter-national attention to this significant urban site. As with the inscription of any site (Meskell 2018: 118–142), significant social, political, and economic elements accompanied the inscription of Meroë. The local impact of inscription was enormous: long-standing villages surrounding and superimposed on top of ancient Meroë were, in some cases, forced to relocate away from the site in order to prepare it as a tourist destination (compare to Zambakari 2017). This disruption in the lives of local inhabitants was unwelcome, particularly since many of the inhabitants served as excavators on past missions at Meroë and felt a deep connection to the site and its archaeology.

Global connectivity, which crosscuts political, institutional, corporate, cultural, and economic lines, is also evident in the inscription of Meroë. At about the same time that Meroë was inscribed, Sudan experienced an enormous influx of infrastructure development funding from China and the Gulf states. Omar Hassan al-Bashir, the president of Sudan at the time, accepted Chinese funds and technical assistance to renovate the outdated railway system. The enhanced rail system runs alongside and crosscuts the site Meroë, overlaying the British rail system that preceded it (cf. Welsby 2011). There was hope that this updated rail system would help to transport tourists to the site, although some of the Chinese firms have since withdrawn from work in Sudan.

Gulf state funds, most notably from Qatar, provided critical support for Sudan when it lost its oil output in 2011 with the succession of South Sudan. Qatari funds supported the former president al-Bashir, the military, development, and also active archaeological research in the form of the Qatar and Sudan Archaeological Project (QASAP). Contemporaneous with the inscription of Meroë, several international expeditions acquired funding from the Qatar Fund and leading to the creation of QASAP. The formation of QASAP, as well as a working group on Meroë and its immediate environs, has created substantial new cohesion between the international and Sudanese projects working in the region. Additionally, QASAP funded the construction of a new visitor center for the Archaeological Sites of the Island of Meroë, which opened in 2019. Information panels at the visitor center describe the Royal City, iron working, and other aspects of the Meroitic economy in English and in Arabic.

Future Directions

There are numerous ongoing missions in the city, the cemeteries, and the surrounding landscape of Meroë. These ongoing projects include the aforementioned ones that examine metal production, previously excavated material culture and texts, the so-called Royal Baths and their environs, and the Temple of Amun. There are also additional projects that have just begun to publish their findings. For example, the Meroë Pyramids Graffiti Project (Qatar – Humboldt Universität zu Berlin) brings together international scholars, archival material, and new field research to document in detail the graffiti corpus on the pyramids that spans more than two millennia (Reidel et al. 2016). Conservation work at the pyramids of Meroë is ongoing (Qatar – NCAM – DAI Berlin). This work includes a re-examination and reopening of pyramids Beg. S. 503 and Beg. N. 9. The findings from this re-examination will be published fully. The surrounding landscape has also been subjected to further survey and examination. For example, the Meroë Quarries Graffiti Project (2105, UCL Qatar), led by Brigitte Cech, examines the sandstone quarries in the vicinity of Meroë, including the graffiti. The publications for this project are forthcoming.

Mesa Verde

Paulette F. Steeves
Department of History and Philosophy, Algoma University, Sault St Marie, ON, Canada
Mount Allison University, Sackville, NB, Canada

Introduction

Mesa Verde is a national park located in Montezuma County, southwestern Colorado, USA. The park is famous for its numerous well-preserved cliff dwellings, mesa top pit houses, kivas, and multistoried structures. In the late 1880s, Virginia McClurg, a journalist who first visited the area in 1872, began to lobby federal representatives to create federal parks status for the Mesa Verde area (NPS website). No national park honoring an archaeology site or humanly constructed landscape had been considered in the United States. However, due to McClurg's fierce decades long lobbying, President Roosevelt signed the bill into law on June 29, 1906, and Mesa Verde National Park finally came into existence (NPS website). Mesa Verde was nominated to the US National Register of Historic Places in 1966 and was named a UNESCO World Heritage Site in 1978.

The park contains 4700 archaeological sites including 600 cliff dwellings. The cliff dwellings vary in size from one-room storage spaces to multifamily dwellings of more than 150 rooms. The park encompasses 52,000 acres of land with the highest elevations ranging from 6000 to 8572 ft (1000–2613 m) above sea level (NPS 201).

Region

Mesa Verde is Spanish for "green table." The park is in an area of the United States commonly referred to as the four corners where the borders of present-day southeast Utah, southwest Colorado, northwest New Mexico, and northeast Arizona meet. The four corners area contains many ancient Puebloan archaeological sites with pit houses, cliff dwellings, kivas, towers, and petroglyphs. Mesa Verde National Park has one impressive petroglyph panel known as "Petroglyph Point" that is accessible by a 2-mile trail (BLM 2012). Throughout the park there are well-marked automobile tour routes, viewing areas, and trails which lead to numerous pit houses, cliff dwellings, and kivas (Fig. 1).

Mesa Verde, Fig. 1 Mesa Verde cliff dwelling. P.Steeves 2012

Pit Houses

Archaeologists believe that the area of Mesa Verde Park was first settled by ancient Puebloan people around AD 500 National Park Foundation (NPF 2017). The mesa tops offered productive agriculture areas where Puebloan people grew corn, squash beans, and other food crops. The earliest structures at Mesa Verde were pit houses which were located on the mesa tops. The pit houses were usually oblong or round and were semisubterranean with floors dug into the soil several below surface level. The roof of a pit house consisted of a wood frame covered with brush, grass, thin poles and capped with mud. The pit house was usually being divided into two rooms, the living space which had a fire pit located beneath a center hole in the roof that served as a chimney and an entry way (NPS 2012) and a smaller second room used for storage. Mesa Verde Park has constructed permanent

buildings over a few excavated pit houses which protect them from the environment and allow the public to view the interior of the structures (Fig. 2).

Kiva

Archaeologists commonly agree that ancient Puebloan kivas were used for religious purposes as they are today within modern Puebloan communities. Kivas held a prominent place in ancient Puebloan communities and are assumed to have been used mainly for ceremonies; however, they may have held different or diverse functions across time. Most kivas were constructed as underground structures, but there are also aboveground and tower kivas. The larger cliff dwellings at Mesa Verde have numerous kivas in each community area (Fig. 3).

Mesa Verde, Fig. 2 Pit House reconstruction at Step House Ruins, W.?V. Bailey 2007. http://commons.wikimedia.org/wiki/File:Pithouse_at_Step_House_Mesa_Verde_1.jpg

Cliff Dwellings

The cliff structures of Mesa Verde are believed to have been built and occupied sometime after 1100 AD, a time archaeologists have designated as Pueblo II. There are 600 cliff structures which have been recorded in Mesa Verde Park. Some of the cliff dwellings were large villages of multistoried apartment like structures, built in a step design with balconies and open areas. These village areas consisted of family dwellings, communal areas, kivas, storage rooms, and towers. Puebloan cliff structures at Mesa Verde were constructed of stone, adobe, mud, and other materials such as wood.

Visitors to the park have the option to walk through some of the cliff dwellings on a park ranger-guided hike. Chapin Mesa has many cultural sites including Balcony House, Sun Temple, Square Tower House, and Spruce Tree House which has 130 rooms including 8 kivas (Fig. 4).

Cedar Tree Tower. Cedar Tree Tower is one of several tower sites that are located on the mesa tops (Lamb 2001). On Wetherill Mesa, there are views of Step House which has one of the largest concentrations of petroglyphs found in the park, Mug House which has 94 rooms clustered around a large kiva, Long House which has 150 rooms and 21 kivas, Kodak House, Two Raven House, and the Badger House community area (Lamb 2001). The largest cliff dwelling in Mesa Verde Park is Cliff Palace with 150 rooms, 21 kivas, and 75 open areas (Fig. 5).

Ninety percent of Mesa Verde's cliff dwellings are smaller structures of less than ten rooms. The larger cliff dwellings include Cliff House with 150 rooms, Long House with 150 rooms, Spruce

Mesa Verde, Fig. 3 Interior of Kiva of Mesa Verde, Wikimedia Commons 2012. http://en.wikipedia.org/wiki/File:Kiva.jpg

Mesa Verde, Fig. 5 Cliff Palace. P?Steeves,?2012

Tree House with 130 rooms, and Balcony House with 40 rooms (NPS 2012). The larger community areas are often discussed by archaeologists as villages.

The ancient Puebloan people were very successful farmers (BLM 2012); they constructed dams and water systems for agricultural and community use. Archaeologists believe that the Ancestral Puebloan occupation of Mesa Verde ended around AD 1300 possibly due to a severe drought.

Historically early settlers and archaeologists referred to the Puebloan peoples of Mesa Verde as the Anasazi Culture. However, no indigenous community or group ever called themselves by that name. Anasazi is a Navajo word: in Navajo [Anaasazi "anaa (enemy), sazi (ancestors)"] (Hewit Institute 2012). The identity of the cliff dwelling people as Anasazi, though formerly established in archaeological terminology and embedded in dominant discourses on the area, is offensive to modern Pueblo people who consider it an ethnic slur (BLM 2012). The descendants of the ancient Puebloan people who lived at Mesa Verde are recognized today as the Hopi, Zuni, Acoma, and Laguna.

Mesa Verde contained thousands of artifacts including Puebloan pottery which is very distinctive in style and decoration. Early explorers, unfortunately, looted the sites and took boxcar loads of pottery and artifacts to museums and private sales in Europe. After the area became a national park in 1906, the pottery and artifacts that remained were afforded protection. Mesa Verde Park today houses over three million artifacts including pottery, tools, baskets, and sandals (BLM 2012). The United States National Park Service has an active Archaeological Site Conservation Program (ASCP) at Mesa Verde which includes the collection of survey data on all sites in the park and assessments of over 200 of the park's 600 cliff dwellings. The park also has an active program to stabilize and protect sites from the damaging effects of natural elements such as wind and rain.

Mesa Verde is an extensive archaeological area; the main cliff dwelling and some pit houses can be visited in 1 day if you drive a car along the loop road tours. The park has a full-service hotel and restaurants, stores and laundry facilities, and camping area which is located at the entrance to the park.

Meskell, Lynn

Rosemary A. Joyce
Department of Anthropology, University of California, Berkeley, CA, USA

Basic Biographical Information

Lynn Meskell (Fig. 1) is an Australian-born archaeologist who completed her Ph.D. at Cambridge University in 1997. Currently Professor of Anthropology at Stanford University, she was previously a faculty member at Columbia University (1999–2005) and a Postdoctoral Fellow at Oxford University (1997–1999). Meskell received her B.A. from the University of Sydney in 1994, having also studied Egyptology at Macquarie University. While an undergraduate, she assisted in archaeological fieldwork in New South Wales, Australia, in Micronesia, and in Cyprus and Greece. At Cambridge, Meskell participated in field projects in the Egyptian East Delta and took part in the Cambridge Theban Mission in Luxor. In her doctoral dissertation, Meskell analyzed data from the cemeteries of Deir el-Medina, a New Kingdom worker's village across the Nile from Luxor.

Meskell's postdoctoral field research involved a return to Egypt, where she codirected the South Saqqara Survey Project in 1998 and 1999. With her appointment as Assistant Professor at Columbia University in 1999, she became the field director of the Columbia University Excavations at Amheida, Egypt, in 2000. In 2001, Meskell obtained funding from the National Science Foundation to explore the potential of digital technologies for visualization of heritage sites, initially with her Egyptian project. She continued her work with digital technologies but switched her research site to South Africa in 2003. This marked a turning point that saw her shift her focus from Egyptian antiquity to the contemporary production of "heritage" in post-apartheid South Africa.

Meskell continues participation in field archaeology, as director of the Çatalhöyük Figurines Project. The project aims to overcome a history of representation of figurines from this important early Neolithic site that has focused on a small range of images that support particular interpretations related to fertility and mother goddesses, for

Meskell, Lynn, Fig. 1 Lynn Meskell

example, showing that animal figures are more common than previously understood (Meskell 2008).

On her graduation from the University of Sydney, Lynn Meskell was awarded the University Medal. Her postdoctoral appointment at Oxford was supported by the Harold Salvesen Research Fellowship. She began work in South Africa with funding as a Research Fellow by the South African National Research Foundation in 2002. In 2002, she was also a National Endowment for the Humanities Fellow at the School for American Research (now the School for Advanced Research) in Santa Fe. Meskell received the Andrew W. Mellon Foundation's New Directions Fellowship in 2004, supporting training in ethnography and African studies to prepare her for work in South Africa.

Major Accomplishments

Meskell is recognized for her contributions to feminist archaeology, archaeological ethics, and issues of heritage. In the 1990s, Meskell established herself as a critical voice in the archaeology of women, gender, and the body. Her 1996 article in the *Norwegian Archaeological Review* on what she termed the "somatization" of archaeology was a call to engage with broader social theory. Meskell (1996) wrote that archaeologists' emphasis on power, particularly the work of Michel Foucault, came at the expense of individuality and agency. She advocated viewing "embodied persons" as foci where biology, culture, and experience intersected. Her emphasis on the necessity to consider individuals carried through in later works, such as *Archaeologies of Social Life* (1999), where she used the cemeteries of Deir el-Medina to talk about personhood in ancient Egypt. The book explored the intersection of multiple dimensions of social difference, including age, sex, and class, in the lives of the buried individuals.

The publication of her edited book, *Archaeology Under Fire*, (Meskell 1998) initiated one of her most enduring emphases: exploration of the social and political contexts within which archaeology is carried out and through which archaeological knowledge circulates. In her contribution for a 2002 conference on ethics in anthropology sponsored by the Wenner-Gren Foundation for Anthropological Research (Meskell and Pels 2005), Meskell drew attention to the way contemporary residents were alienated from locations viewed as sites of heritage by the state and by archaeologists as well.

After the 2001 attacks on the World Trade Center in New York, Meskell (2002) published an influential article proposing a concept of "negative heritage": "a conflictual site that becomes the repository of negative memory in the collective imaginary" (Meskell 2002: 558). Juxtaposing analysis of the World Trade Center site and the Bamiyan Buddhas, destroyed by the Taliban government of Afghanistan, Meskell demonstrated the need for more critical debate that acknowledged the equivocal nature of material marking of pasts. In her most recent book, Meskell (2011) takes the central concept of this earlier article – "past mastering" – as a beginning for understanding post-apartheid heritage development in South Africa. Using ethnographic methods, Meskell traces how archaeology and wildlife intersected in the development of tourism for the new South Africa. She says that the project became "about why natural heritage and conservation has trumped the cultural past, why nature is seen as global and all embracing and non-racial" (Bailey 2011: 11).

Meskell is continuing research on heritage policy in the contemporary world, through an ethnography of UNESCO. She argues that archaeologists, despite working in and around World Heritage Sites, have very little understanding of how UNESCO operates (Bailey 2011: 8–9). By providing an ethnographic account of UNESCO (Meskell 2012), following on her ethnography of heritage in South Africa, Meskell is defining a new field for archaeological ethnography, going beyond the now common approach of conducting ethnography in communities local to archaeological sites and projects.

In a 2011 interview, asked to single out the work for which she would like to be remembered, after mentioning *Archaeology Under Fire*,

Meskell noted that she was proudest of her role as a founding editor for the *Journal of Social Archaeology* "because it promotes such good work by people from all over the world" (Bailey 2011: 12). The globalization of archaeology promises to be a lasting contribution of her work as both writer and editor.

Mesoamerica in the Classical Period

Charles C. Kolb
Division of Preservation and Access, National Endowment for the Humanities, Washington, DC, USA

Introduction

Mesoamerica as a geocultural concept was defined by archaeologist Paul Kirchhoff in 1943 as a culture area in the Americas extending from central and west Mexico to Belize, Guatemala, El Salvador, Honduras, Nicaragua, and northern Costa Rica. The area is defined by a mosaic of cultural traits developed and shared by its indigenous cultures since ca. 7000 BCE, within which pre-Columbian societies flourished into the era of Spanish colonization and into the historic present. Archaeologists divide Mesoamerican civilizational development into three primary chronological periods: the Preclassic (PreClassic or Formative) period extending from ca. 1500 BCE to CE 300, the Classic period extending from approximately CE 150 to 950, and the Postclassic (PostClassic) period extending from ca. CE 950 to 1521. Some scholars employ designations of Terminal Classic for the period 800–900/1100 or

Charles C. Kolb has retired.

Epiclassic (Epi-Classic) for the era 800–1200 to indicate a transition between the Classic and Postclassic. All of these generalized dates differ from region to region and site to site. More precise chronologies of Classic period sites are detailed below when the authors are able to refine the generic dates with absolute or relative chronologies derived from radiocarbon analyses, dates on inscribed monuments, or ceramic studies.

Definition

Classic period Mesoamerica was an era of great social development and cultural interaction and commerce. It is characterized primarily by human adaptation to settled life, the creation of major cities located from arid highlands to tropical lowlands, as well as advancements in domesticated cultigens, amplification of sophisticated social structures, modification of both the landscape and natural ecology, as well as traditions of gardening in different environments, increased production of maize and other food resources, construction of sacred monumental architecture, and art, including ceramics, lithics, and murals.

There are voluminous published and online resources available on Mesoamerica in the Classical era: Carrasco et al. (2002), Evans (2013), Evans and Webster (2013), Nichols and Pool (2012), Sanders et al. (1979), Scarborough and Clark (2007), Sharer and Traxler (2006), and Williams and Maldonado (2016). For contextual background and useful but dated overviews, see Wauchope's (1964–1976) *Handbook of Middle American Indians* (16 vols.) and Weaver's (1993) classic textbook treatment.

Geography and Ecology

Ecological factors – the physical and biological environments, topography, altitude, hydraulic and mineral resources, native flora and fauna, cultigens, and human resources – played a significant role in the flowering of Mesoamerican cultures during the Classic period (Sanders et al. 1979). For purposes of presentation and discussion, Mesoamerica is divided into the following geographical units: Central Highlands, West Mexico, Gulf Coast Veracruz, Valley of Oaxaca, and Lowland Maya and Highland Maya. Some scholars further divide the Maya area into four principal geographic zones: (1) the Pacific coastal plain and piedmont which merge into (2) the northern highlands in contemporary Guatemala and Chiapas which merge into (3) the southern and central lowlands, or Petén, and further north into (4) the northern or Yucatán lowlands.

Major Classical Period Polities

Central Highlands

The Central Highlands during Mesoamerican Classic period (200–550) is characterized by city-states in the Basin of Mexico and adjacent regions and West Mexico (Carrasco et al. 2002; Cowgill 2015; Evans 2013; Kolb and Sanders 1996; Sanders et al. 1979; Scarborough and Clark 2007). Teotihuacan, a civic-ceremonial center located in a valley of the same name in the northeastern Basin of Mexico, was established ca. 100 BCE and with continuous construction through 450 grew to become the sixth largest city in the world. Teotihuacan's initial inhabitants had an Otomi ethnic origin but included multiethnic immigrants who came from areas influenced by Teotihuacan civilization, including Zapotec, Mixtec, and Maya peoples, as well as Nahuas and Totonacs. The city encompassed 24.5 km^2 and had at least 125,000 residents (with possibly as many as 200,000 inhabitants) at its apogee; the immediate rural area also included 134 other habitation sites (varying from farming hamlets to large nucleated towns) with an additional 40,000 persons. The city, center of a pan-Mesoamerican empire established through commerce and military conquest, was also supported by political, religious, and socioeconomic linkages to other centers located in the Gulf Coast, the Yucatan Peninsula, Valley of Oaxaca, and West Mexico. For centuries Teotihuacan was the dominant power in the Basin of Mexico, and the empire encompassed an area that reached north as far as the present-day US

Southwest, west to the Pacific coast, east to the Gulf of Mexico, and south as far as Honduras. Teotihuacán's influence in Mesoamerica was of three types: political-military, economic, and ideological-religious. Politically and militarily the city directly ruled most of the central highlands, including the densely populated Basin of Mexico, which saw the population increase dramatically due primarily to immigration from outlying areas that were encompassed within the polity.

Multi-ethnic Teotihuacan society had a well-defined social stratification, monumental architecture, temple pyramids, palaces, platforms, plazas, altars, terraces, more than 2200 multi-family residential complexes with patios and surrounding rooms, tombs for royalty, mortuary caches, and extensive craft specialization in stone working (obsidian), jewelry, pottery, and textiles. Major site features include the Pyramid of the Moon, Pyramid of the Sun, Ciudadela (Citadel), Temple of the Feathered Serpent, and Gran Conjunto (market) all situated along the city's main north-south axis the Avenue of the Dead. In addition to large-scale urban planning, Teotihuacan's unique architecture featuring the *talud-tablero* (inward-sloping surface or panel called the *talud*, with a panel or structure perpendicular to the ground sitting upon the slope called the *tablero*) was commonly used in platforms, temples, and pyramids in pre-Columbian Mesoamerica and became popular in the Early Classic Period of Teotihuacan. The *talud-tablero* is also found on buildings in Maya regional centers (Tikal, Kaminaljuyu, Copán, Becan, and Oxkintok) and Petén Basin sites influenced by Teotihuacan's commerce and conquest. Maya hieroglyphs on stelae for the year 378 document Teotihuacan's conquest of Tikal while year 426 designated the conquest of Copán and Quiriguá. Other Classic period traits are water-control technologies, a distinctive polychrome mural art, and the control of obsidian resources (hence, tool fabrication and distribution). Teotihuacan was also distinguished by its ceramic assemblage – both produced locally and imported – as well as fired clay artifacts including figurines and small incense burners made in local workshops and large elaborate censers made in workshops controlled by elite priests. Droughts and climate change beginning in 535–536 (supported by dendrochronology and ice core analysis) caused malnutrition. An internal uprising ca. 550 or later resulted in the sacking and burning of elite residences and defacing of major monuments along the Avenue of the Dead. Nearby centers such as Cholula, Xochicalco, and Cacaxtla competed to fill the power void left by Teotihuacan's decline.

Xochicalco in western Morelos was initially occupied in 200 BCE, but the Olmeca-Xicalanca (Maya traders from Campeche) founded a fortified city-state with a major urban center during Epiclassic (650–900). The site has step-pyramid temples, palaces, three ballcourts, sweat baths, circular altars, and an astronomical observatory and served as a commercial center with craft production emphasizing obsidian. It was later burned and destroyed and then abandoned and recolonized ca. 1200 by Nahua-speaking Tlahuica. Cacaxtla, located in Tlaxcala, prospered during the Epiclassic Classic (650–900) as the capital of a region inhabited by the Olmeca-Xicalanca. It is best known for colored murals painted in Maya style combing the symbolism of Teotihuacan with Maya, Mixtec, and Totonac influences.

Cholula in the Puebla-Tlaxcala Valley was occupied from the Early Formative period through Postclassic, serving as a Late Classic regional center (500–700). During this period, Cholula was a major center contemporaneous with Teotihuacan but avoided that city's fate of violent destruction at the end of the Classic period. Classic period Cholula had a maximum extent of 5 km^2 and estimated population of 15–20,000. The Great Pyramid of Cholula is the largest archaeological pyramid (temple) in the New World (400 $\times$ 400 m) built in an architectural style linked to Teotihuacan and El Tajin. Cholula reached its maximum size and population during the Postclassic period.

West Mexico

In West Mexico, the Bajío tradition, a regional culture identified in Guanajuato, Zacatecas,

Querétaro, Colima, Nayarit, Hidalgo, Mexico, Michoacán, and Guerrero has an Early Classic apogee (Williams and Maldonado 2016). Late Classic evidence is noted in Morelos, Tlaxcala, and Puebla, and an Epiclassic is reported in Morelos and Tlaxcala. The Bajío tradition is characterized by small city-states or kingdoms with architecture and ceramic works distinct from other Mesoamerican cultures. Trade networks, ballcourts, circular structures, sunken patios, and double temples are features of this tradition. In the Late Classic, the small city-states declined and collapsed as the result of the overexploitation of the surrounding deciduous rainforest and much of the region was abandoned by ca. 900 as the Postclassic Toltec city of Tula arose. West Mexico (Nayarit, Jalisco, and part of Colima) is also the region of a lesser-known Teuchitlan tradition which spans the Early-Middle Formative through Postclassic eras (300 BCE-CE 900) with an Early Classic 200–400 abruptly terminated by the end of the Classic by the ascent of the Postclassic Tarascan state. It was a ranked state society but politically fragmented. The major Teuchitlan site Los Guachimontones had multi-level circular step pyramids, rectangular plazas, ballcourts, shaft tombs, and obsidian workshops. One of the most important innovations in Mesoamerica during the Late Classic or Epi-Classic periods was copper metallurgy.

Lowland and Highland Maya

Independent Classic Maya centers developed in the Yucatecan Lowlands and Highlands during the Early Classic period (200–600) within the modern Mexican states of Yucatan, Campeche, and Quintana Roo and nations of Belize, Guatemala, and western Honduras. This era is considered the apogee of Maya civilization (Carrasco et al. 2002; Coe and Houston 2015; Houston and Inomata 2009; Sharer and Traxler 2006). These polities are characterized by small spatially and demographically independent centers in the form of city-states or kingdoms with dynastic rulerships, well-defined social stratification, civic-ceremonial centers, and monumental architecture (temple pyramids, palaces, platforms, plazas, altars, stelae, ballcourts, terraces, residential complexes – some with patios and surrounding rooms, tombs and sarcophagi for royalty, mortuary caches, mural painting, sacbes (causeways), water-control technologies, and craft specialization in stone working (flint, obsidian, and greenstone), jewelry, pottery (polychrome ceramics), and textiles. Notable unique features include distinctive writing and calendric systems, hieroglyphics, scholarly astronomical reckonings, dated monuments, and corbelled vault architecture. The troubled period of 650–900 that followed the break-up of the great Mesoamerican states such as Teotihuacan, Monte Albán, La Quemada, Palenque, and Tikal. This period, from ca. 650 to 900, is known as the Epiclassic period. The Late Classic period (650–900) is represented in sites within Yucatan, Chiapas, and Guatemala.

Major Early Classic Maya centers include Calakmul, Caracol, Chunchucmil, Copán, Palenque, Quiriguá, Tikal, Uaxactun, and Yaxha. Major Late Classic Maya centers were Aguateca, Cancuen, Cobá, Dos Pilas, La Blanca, Pusilhá, Toniná, Uxmal, Waka', Xultún, and Xunantunich.

Terminal Classic Maya area centers include the following: Puuc Region (Kabah, Labna, Sayil, and Uxmal) and Petén Basin (El Chal and Seibal).

Valley of Oaxaca

The Zapotec civic-ceremonial-citadel site of Monte Alban is located in the central section of the Valley of Oaxaca at an easily defended location where the northern Etla, eastern Tlacolula, and southern Zimatlán and Ocotlán valley branches converge. It was founded toward the end of the Middle Formative period (ca. 500 BCE), and by the Terminal Formative (ca.100 BCE–CE 200), Monte Alban had become the capital of the large-scale expansionist polity that dominated much of the Oaxaca highlands (Kolb 2011; Marcus and Flannery 1996; Sanders et al. 1979). Monte Alban had its apogee ca. 700–900; thereafter Early Postclassic Mitla (900–1400) and then Late Postclassic Zaachila (1400–1521) attained control (Coe and Houston 2015; Houston and Inomata 2009). The ancient capital was largely abandoned by 800–950. Monte Albán's Classic period is characterized by Oto-Manguean languages, an Early

Classic (200–500) expansion by colonization and conquest, and a Late Classic (500–750) which incorporated Teotihuacan deities (Feathered Serpent, Butterfly God, and Rain/Storm God) and the Nahuatl god of spring Xipe Totec. Other cultural features included dynastic rulership and social stratification; civic-ceremonial centers and monumental architecture with temple pyramids, palaces, platforms, plazas, altars, ballcourts, terraces, dams, canals, and residential complexes; 170+ tombs for royalty; mortuary caches; and craft specialization in stone working (flint, obsidian, and greenstone), jewelry, pottery, and textiles. The Great Plaza (ca. 300 × 300 m) has civic-ceremonial and elite-residential structures located around it or in its immediate vicinity, with 300+ carved stone monuments (*Danzantes*). Other unique features are a glyphic writing system, calendrical notation, and ancestor worship.

Gulf Coast Veracruz

Gulf Coast Classic culture is centered on northern and central areas of present-day Veracruz state and existed during the Early and Late Classic (100–1000 CE) exemplified by the site of El Tajin with its unique Pyramid of Niches and smaller regional centers at Cerro de las Mesas, Higueras, Nopiloa, Remojadas, and Zapotal (Coe and Houston 2015; Sharer and Traxler 2006). This culture is characterized by heightened militarism, human sacrifice, and the Mesoamerican ballgame (22 ballcourts at El Tajin). Other characteristics include elite hereditary rulership, social stratification, monumental architecture and sculpture, (temple pyramids, palaces, plazas, and altars), residential complexes, trade networks, and craft specialization in stone working and pottery (figurines).

State of Knowledge and Current Debates

Introduction

In 1943, Paul Kirchoff introduced the term Mesoamerica to identify a culture area that, at the start of the Spanish Conquest around 1519, was occupied by numerous indigenous societies who shared a suite of collective cultural and linguistic practices (Kirchoff 1943). His purpose was to provide a conceptual and spatial entity for anthropologists and archaeologists to organize the study of these societies. Initially, the boundaries of the area were based on linguistic and ethnographic information that existed at the time of European arrival. Since then, archaeological and anthropological research has added substantial new data that have modified the meaning and use of the term to more accurately represent and define the region. Today, Mesoamerica is recognized as a complex cultural concept whose spatial boundaries expanded and contracted as shared cultural practices ebbed and flowed across time and space (Clark 1997: 216).

Mesoamerica was a cultural hearth where numerous linguistic and ethnic groups emerged and evolved. These individual groups shared a suite of common traits and characteristics that included calendar systems and astronomical observations, a ballgame played with a rubber ball, ritual activities such as human sacrifice and self-immolation, ancestor veneration, deity worship, shamanism, and maize agriculture among others. Not every group practiced all of the cultural facets or to the same degree, but most participated to a level sufficient to be considered part of the culture area. Spatially, the boundaries of Mesoamerica were dynamic not constant or fixed. As processes of fission and fusion occurred among and between societies, the margins of Mesoamerica expanded and contracted. Thus, the boundaries of the Mesoamerican culture area were dependent upon the temporal period under consideration.

As a cultural continuum, Mesoamerica began to emerge during the transitional period between the late Archaic (c. 3500 BC) and the Early Preclassic period (c. 2000 BC). It was during this time that the move toward sedentary, agriculture-based societies allowed for the initial development of cultural traits and characteristics that would come to distinguish Mesoamerica. By the end of the Preclassic period (c. AD 150–250), social stratification, subsistence systems, worldviews, and other societal elements would be commonly practiced across many portions of an expanding Mesoamerica. This development would continue, unevenly, through to the Classic (c. AD 250–1000) and Postclassic periods (c. AD 1000–1519), when Mesoamerica would reach its greatest extent encompassing the north-central latitudes of Mexico to the south and southeast through Guatemala and Belize, portions of Honduras, El Salvador and Nicaragua, to the Gulf of Nicoya in Costa Rica (Gossen et al. 2007; Canto Aguilar and Castro Mendoza 2010) (Fig. 1).

The interregional consistency in the adoption and presentation of these sociopolitical and ideological elements is remarkable when one considers that Preclassic Mesoamerica was culturally, linguistically, and environmentally diverse (Clark et al. 2010: 4; Reilly 1995). These settlements occurred in detached, distant localities that formed "an archipelago of complexity," areas of higher social complexity that were interspersed

Mesoamerica in the Preclassic Period: Early, Middle, Late Formative, Fig. 1 Map of Mesoamerica with regions mentioned in text identified

across the landscape (Rosenswig 2010: 7). These locations were probably connected through elite interaction that took the form of long-distance exchange and acquisition networks for objects and goods (e.g., obsidian, jade, iron-ore, shell, and iconic ceramic vessels and figurines) that had been in place prior to the Early Preclassic period (Clark 1991; Flannery 1976). Over the period different, geographically oriented interaction spheres were established and maintained by numerous, rapidly emerging, socially complex polities.

A key question regarding the development of Mesoamerica involves how these various traits and characteristics emerged, evolved, and spread. Theorists portray the development of sociopolitical complexity as a process in which environmental, social, political, economic, ideological, and demographic variables acted independently or in combination to bring about change. Thus, Mesoamerica is best understood as a mosaic of individual pieces that, on the surface, may exhibit differences in adaptation and practice but are all bonded to an underlying framework by a socially consistent template. Interpretive difficulties have been a result of disparities in the extents and intensities of regional research programs. For example, the Maya have been rigorously investigated for more than a century and a half, but researches into the cultures of West Mexico are only recently gaining recognition (Beekman 2010; Pollard 1997; Williams 2004). The findings of West Mexican archaeological research are also changing perceptions of its role in the

development of Mesoamerica and its relationship to other regions.

One explanation for the adoption and distribution of cultural traits may be seen in the long-distance exchange and acquisition of goods and materials. The procurement of utilitarian items can be expected and is known to have occurred prior to the Preclassic period. The presence of non-local, non-utilitarian items (e.g., elite-related goods of jade, marine shell, amber, or iconic ceramics) during the Preclassic, however, raises questions as to their transport, significance, and purpose. Jade is an excellent example of a geographically diagnostic material that has been uncovered across Preclassic Mesoamerica. Note that Mesoamerican jade (jadeite) is a geological product and its only known source is the Motagua River Valley in Guatemala, but its pan-Mesoamerican presence extends from West Mexico (Beekman 2010; Mountjoy et al. 2004) to Costa Rica (Jones 1998). The distribution and pervasiveness of this material required complex long-distance interactions. Often, similar greenstones (e.g., serpentine, quartz, greenschist, chlorastrolite, or olivine) are often referred to as "social" jade more common and are found naturally across Mesoamerica.

By the Preclassic period, the content of the interregional networks had expanded beyond purely economic relationships to one that conveyed a suite of sociopolitical, technical, and ideological components as well. The items, technologies, and ideas that moved through these networks cross-cut a diversity of ethnic groups across an uneven physical landscape (Reilly 1995: 29). The materialization of some or all of these elements by a settlement's leadership could be used to support, facilitate, and validate their courses of civil action (see Helms 1979, 1993). Public displays of exotic objects, performance of highly ritualized ceremonies, and construction of architectural features were ways in which Preclassic leaders substantively demonstrated their acceptance of the principles borne within the interaction sphere and used them to advance their position within society (Reilly 1995; Smith and Masson 2000: 363). Participation enabled elite leaders to accumulate wealth and power by making exotic prestige items and valued commodities accessible to peers and constituents (Pool 2007: 290–293) and were used to construct and shape the social hierarchy (Hirth 1992). For these socioeconomic reasons, there was an increase in participation that intensified the demands for esoteric and exoteric demonstrations of power and privilege (Cheetham and Blomster 2010; Diehl and Coe 1995: 23; Grove 1993: 97–102; Grove 2007: 220).

Debate regarding the role of the Olmec of the Southern Gulf Coast lowlands during the Preclassic period has transpired for nearly a century (de Antropología 1942; Blomster et al. 2005; Diehl 2000, 2004; Flannery 1968; Graham 1989; Lowe 1998; Pina-Chan 1989; Pool 2007; Sharer and Grove 1989). The Olmec have been credited with a number of Mesoamerican "firsts" (e.g., the first established complex society, the first great Mesoamerican art style, the earliest monumental public works programs, the first city, and arguably the first state). Details of these unprecedented features have been argued. Nevertheless, there is little question that the ancient Gulf Coast Olmec played a key role in the development of Mesoamerica as a culture area (see Pool 2007; Cheetham and Blomster 2010; Clark and Pye 2000; Coe et al. 1995; Coe and Koontz 2013: 61; Diehl 2004).

The Olmec are an archaeological culture identifiable in the archaeological record by a shared array of concepts, values, and practices that established a communal worldview and imparted meaning to their cultural and physical surroundings. The Gulf Coast Olmec were not a homogeneous or uniform entity across space and time, however. Perceived similarities in style and symbolism led to an early, simplistic view of the Olmec as a static, monolithic entity; whereas recent investigations show that local elites and leaders of sociopolitical centers along the coast selectively employed various traits and characteristics to meet the demands of their constituency (Diehl 2004; Doering 2007; Pool 2007). In the latter stages of the Preclassic period, they may have even altered their form of government in order to extend the survival of their society (Wade 2017a).

Timeline of Mesoamerica

"In the late nineteenth century, there was really no idea at all of the sequence of development in pre-Spanish Mexico" (Coe and Koontz 2013: 39). We now know that prior to the establishment of Mesoamerica as a culture area, humans had occupied the region for millennia (Coe and Koontz 2013: 18–38). Although the date for initial occupation remains under debate, it is generally agreed that the age of Paleo-Indians or Early Hunters lasted until roughly 7000 BC, when small nomadic bands of hunter gathers roamed the territory. During the ensuing Archaic period (c. 7000–2000 BC), people began to domesticate food plants including maize, which would become the mainstay of the Mesoamerican diet. Mesoamerica as a social entity can arguably be said to have begun around 2000 BC, when more sedentary village life took hold, ceramics were introduced, and common cultural traits and characteristics began to emerge.

The chronology of Mesoamerica is divided into three primary segments: the Preclassic (c. 2000 BC–AD 250), Classic (c. AD 250–1000), and Postclassic (c. AD 1000–1519) periods. Unfortunately, these terms can be misleading and are not representative or consistent across the region. Early investigations of Mesoamerica were focused on prominent, visible architectural remains at sites like Teotihuacán, near Mexico City; Monte Albán, in Oaxaca, Mexico; Maya centers, such as Uxmal and Chichén Itzá in the northern Yucatan Peninsula; and Tikal and Copán in Central America (e.g., Caso 1932; Morley 1913, 1917; Thompson 1966). Because of the narrow scope of these initial explorations, broad generalizations regarding the timing and formational processes of the social development at these sites were articulated and applied to all of Mesoamerica. Subsequent research, however, has found that these terms were not appropriate for many other Mesoamerican cultures that had developed along different chronological and cultural trajectories.

The initial simplistic, and ultimately mistaken, belief was that a "golden age" or Classic period was Mesoamerica's cultural highpoint that included planned cities, architectural complexes, hieroglyphic writing systems, development of solar and ritual calendars, monumental artistic achievement, a pantheon of deities and ritualized religious practices, long-distance exchange systems, and advanced agricultural techniques. It was also thought that this cultural zenith had been preceded by a formative phase when naïve societies began to slowly emerge and develop, thus the term the Preclassic. Following the golden era, it was believed that Mesoamerica had experienced an interval of cultural decline called the Post Classic. Recent investigations have demonstrated, however, that most, if not all, of these presumed "Classic" features had actually occurred earlier, in the Preclassic, and that many societies continued or began a rise to prominence during the Postclassic. Therefore, Preclassic, Classic, and Postclassic are now used only as chronological markers, not as descriptive elements of a developmental sequence.

The focus here is on the Preclassic, a chronological designation that spans roughly from 2000 BC to AD 250. This period is also referred to as the Formative period, a 1960s term that was introduced to better express the changes in the material culture (Grove 2007: 213). These two terms are often used interchangeably, but it can be noted that the former is essentially used in reference to the Maya, whereas the latter is largely used as a descriptor for non-Maya regions of Mesoamerica. Nevertheless, there is no hard and fast rule on their use.

Subdividing the Preclassic period into shorter chronological segments varies according to several factors (e.g., radiocarbon (calibrated or uncalibrated) or astral/calendric dating). A generally acceptable partitioning is: Early (c. 2000–1000 BC), Middle (c. 1000–400 BC), and Late (c. 450 BC–AD 250). In turn, these timespans can be separated into more concise durations; for example, late Early Preclassic (c. 1250–1000 BC), early Middle Preclassic (c. 1000–750 BC), or middle Late Preclassic (c. 200 BC–AD 50). In this essay, the term Preclassic is used to describe the entire period from c. 2000 BC to AD 250, while Early, Middle, and Late Formative are used to identify the primary chronological subsegments. Please note, however, that these sequential divisions are arbitrary

chronological markers or guidelines that vary according to the researcher, the ancient society, or the geographic region.

Terminology aside, the Preclassic period was one of the most dynamic in Mesoamerican history. It was a transformative era that saw the emergence, establishment, and dissemination of unprecedented social, political, and economic practices along with ideological conventions and materializations that would serve as the framework upon which all subsequent Mesoamerican societies would be based. During the Preclassic, there were profound transitions that affected every aspect of society (Coe and Koontz 2013: 18–58). Nomadic, egalitarian bands and incipient agricultural societies that had existed for millennia, during the earlier Paleo-Indian and Archaic periods, began a rapid change toward a more sedentary lifestyle in socially ranked villages. The focus of subsistence systems was on full-time agriculture. Populations grew exponentially, and economic specialization and long-distance acquisition of goods and materials expanded. Either as a result of these changes or as a driving factor behind them, the appearance of hereditary inequality and the development of complex societies facilitated the large-scale socioeconomic conversions (see Clark and Blake 1994; Earle 1991; Redmond 1998).

Prelude to the Preclassic Period

The Preclassic period in Mesoamerica was part of a cultural continuum that had begun much earlier. It persisted through the Classic and Postclassic periods, and portions continue to endure today in many parts of Mexico and Central America (Chambers 1977; Gossen et al. 2007). To better understand the changes that influenced or impacted the social, economic, and political transformations that occurred during the Preclassic, consider what had transpired prior to this time. Although details about the Archaic period (c. 7000–2000 BC) in the area of what would become Mesoamerica remain murky, basic knowledge of ancient social structures and subsistence systems illustrate the contrasts in social organization and the conversion of lifeways that would take place in the Preclassic period (Clark and Cheetham 2002). During the Archaic to Preclassic period transition, there was a fundamental change from a seminomadic lifestyle of hunting, fishing, gathering, and incipient agriculture that were characteristic of the Archaic period, to sedentary villages primarily dedicated to full-time agriculture (Michaels and Voorhies 1999; Voorhies 2004). The clan or band-level social structure associated with the Paleo-Indian period gave way to the tribal structure in the Archaic period. By the Preclassic, ranked and stratified societies would become the norm.

These changes may, in part, be attributable to the fact that the beginning of the Archaic Period in Mesoamerica (c. 7000 BC) corresponded with major climatic and ecological deviations including the onset of the Holocene Climate Optimum (HCO), a significant warming period. Concomitant with the HCO was the disappearance of numerous species of large game animals (e.g., mammoth, mastodon, giant bison, ground sloth, camels, and horse) (Prescott et al. 2012). Rapid cultural and material adaptations to these new realities were required for human survival. Subsistence methods turned to the hunting of smaller game and a greater reliance was placed on marine and estuary resources (Lesure 2011; Rosenswig 2006; Voorhies 2004). The collection of specific plant foods increased along with the initial appearance of plant domestication. These modifications meant less travel that allowed more time to be spent in the more productive areas. The combination of these factors may have facilitated the transition to the fully sedentary lifestyle that became the norm in the Preclassic period.

The Early, Middle, and Late Formative periods each witnessed significant, discrete socioeconomic changes. Recent research suggests that major deviations, such as the move to sedentary village life, the appearance of stratified societies, and hereditary inequality did not occur universally or simultaneously across Mesoamerica (Elson 2012; Feinman 2001; González and Winter 2010; Lesure 2011; Niederberger 2000; Williams 2004; Zeitlin and Zeitlin 2000). The origins and expansion of cultural characteristics, technologies, and beliefs were spatially uneven and

temporally irregular. This information precludes the broad generalizations about pan-Mesoamerican occurrences that had previously been established and indicates that an examination of the Preclassic period could be facilitated by observing major changes and events from a synchronic, regionally focused approach.

The Early Preclassic Period (c. 2000–1000 BC)

During the Early Preclassic or Formative period, the characteristic traits that would come to distinguish Mesoamerica as a culture region were materialized. Patterns of social behavior emerged in small, agriculturally based, autonomous tribal villages that were widely scattered across the landscape: along the Pacific coast of Chiapas and Guatemala; the southern Gulf Coast lowlands of Veracruz and Tabasco; the central Mexican highlands including the Basin of Mexico, Morelos, and Puebla; the Valley of Oaxaca; and the highlands and coasts of West Mexico. Incipient ceramic technologies (e.g., slips, pastes, forms, and decorations) and interregional long-distance acquisition routes foreshadowed more complex political economies and developing social inequality. Egalitarian societies sporadically gave way to rank societies where the production, distribution, and consumption of goods and materials were controlled, to some extent, by emergent elite rulers (Clark 1991).

As population centers emerged and evolved during the Early Formative period, the presence of increasing social complexity was expressed in a variety of ways that included artistic and material articulations of wealth, authority, and ideological beliefs. Nevertheless, for all of the regional diversity of expression, there was an underlying uniformity in cultural features and attitudes (e.g., social structures, time keeping, shamanic beliefs and practices, and subsistence systems). The changes were sporadic, however. The timing and degree of change was largely related to the interaction spheres in which people participated. An example of this irregularity is illustrated through a basic regional comparison.

West of the Isthmus of Tehuantepec, small widely dispersed highland villages were primarily dependent upon maize agriculture. Their ceramics and architecture were modest and utilitarian, and social complexity was not readily apparent. To the east of the Isthmus, denser settlement patterns included larger villages with elite residences and ball courts. Ceramics were exceptionally well-made, highly decorated, and varied in form. Beside a utilitarian function, they served as elite vessels for rituals and feasting. The subsistence system included root crops, maize agriculture, and a significant use of wild and natural resources. The development of simple chiefdom societies led by shaman-chiefs is suggested by differential access to goods and resources.

The Soconusco Coast

The emergence of chiefdoms as a political entity represented a key shift in the type of sociopolitical organization seen in early Mesoamerica. Social ranking of individuals was determined by their perceived genealogical distance from the chief whether it be consanguinal (blood ties), affinal (marriage relations), or fictive (fabricated). In this type of social arrangement, the ruler and the community were united within a social network of mutual obligation that was reinforced through economic interdependence and factional commitments (Lesure 2011).

One of the earliest, well-documented appearances of chiefdoms in Mesoamerica took place among the Mokoya, a Mixe-Zoquean speaking culture, centered in the Mazatán region of Pacific coastal Chiapas, known as the Soconusco (Blake 1991, 2011; Clark and Pye 2006). Changes in the regional settlement patterns led to Paso de la Amada becoming the largest in a centralized cluster of villages that were some of the earliest in Mesoamerica. The emergence of social and economic disparities is demonstrated by variations in residences, burial practices, and the presence of exotic and crafted artifacts (Blake et al. 2006; Clark and Pye 2006; Lesure and Blake 2002). These objects were elite goods that signal the existence of a political economy directed by the chiefly elite, who exerted control over their access, production, and distribution.

The earliest ceramic traditions of the Mazatán region of Pacific coastal Chiapas, Mexico were arguably the benchmark of Early Formative

period artisanship (Lesure 1998). The Barra phase (c. 1800–1650 BC) witnessed the initial settlement across the area and the first regional appearance of pottery. Barra phase ceramic vessels were sophisticated in their production, design, and decoration (Clark and Gosser 1995). Additionally, two architectural features at Paso de la Amada demonstrate its development as an early chiefdom society (Clark and Pye 2006). The "Chief's House" (Mound 6) was a broad platform that supported a residence several times larger than the average in the village. The platform and its superstructure were rebuilt in the same location on at least six different occasions over a 200- to 300-year span. Recent interpretations suggest that the structure served both domestic as well as public purposes and was the center of the settlement's ceremonial zone (Blake 2011).

The second major architectural feature at the site was the presence of the earliest known ball court in Mesoamerica (Hill et al. 1998; Hill and Clark 2001). The rubber ballgame is a primary element in Mesoamerican tradition and its role in ancient, historical, and modern times is significant (see Scarborough and Wilcox 1991). The ballcourt, initially constructed and remodeled between 1400 and 1250 BC, was composed of two parallel mounds bordering a 77 m-long alleyway. The essential characteristics of this design would be generally adhered to in all later Mesoamerican ballcourt construction, indicating that by the Early Formative period a fundamental Mesoamerican architectural concept had already been articulated.

Another site, not far from Paso de la Amada, is Cantón Corralito that requires attention due to its distinctive long-distance association with the Olmec of the Southern Gulf Coast. Work by David Cheetham has shown that, during the later stages of the Early Formative period, Cantón Corralito was established as a colony of the Olmec capital of San Lorenzo, located 400 km to the northwest (Cheetham 2005, 2007, 2010). The site's initial occupation dates back to the Late Archaic period (c. 2500–2000 BC) and continued through Early Formative period (c. 1600–1000 BC). The site was destroyed near the end of this period by severe river flooding that inundated the site and buried it under meters of alluvium. The evidence-based interpretations of the activities and relationships of the site demonstrate an example of the influence of the Gulf Coast Olmec during the Early Formative period.

The Valley of Oaxaca

Developments that transpired in the Valley of Oaxaca provide another perspective on sociopolitical events of Early Formative Mesoamerica (Flannery 1976). Human occupation in the valley can be traced back at the Cueva Blanca rock shelter to least 10,000 BC, at Guilá Naquitz to c. 8900–6700 BC, and at Gheo-Shih to c. 5000–3000 BC. These sites may have foreshadowed the early Mesoamerican villages of the Preclassic period and provide evidence of occupational continuity in the region (Marcus and Flannery 2004). Unpredictable rainfall in the lofty valley (1,500 m elevation) led to unreliable wild food resources that encouraged highland foragers to adopt a more stable agricultural subsistence system (Flannery 1986). Domesticated maize, beans, and squash were present by the beginning of the Early Formative period in the permanent villages that dotted the sparse landscape. At San José Mogote and Tierras Largas, the presence of pottery from the Esperidión ceramic complex (c. 1900–1400 BC) is thought to be some of the oldest in Mesoamerica (Flannery and Marcus 1994). The simple vessels were utilitarian in nature and followed similar production methods as well as comparable form and function.

By the Tierras Largas phase (c. 1400–1150 BC), less than two dozen, small hamlets that consisted of small wattle and daub houses existed. The exception to this pattern was San José Mogote, which was about twice the average size in area and population (Flannery and Marcus 2005). During the San José phase (c. 1150–850 BC), the village was the center of a chiefdom and emerged as the ritual and economic hub of the valley. Within the developing social and political hierarchy, the elite controlled the procurement, production, and distribution of items crafted from local and distant materials (e.g., iron-ore, marine shell from the Pacific coast, and obsidian from central Mexico and Guatemala).

The presence of the earliest defensive palisade in Mexico, along with other evidence, suggests that the acquisition and maintenance of power and prestige in the valley required coercion or conflict with neighboring communities. This situation appears to be anomalous when considering other Early Formative period regions where allusion to warfare is, at best, questionable. Perhaps, due to the limited and restricted resources in the valley, the potential for conflict should not be unexpected, and the use of physical force would become a prominent part of the valley's subsequent history.

West Mexico

The beginning of the Early Formative period in West Mexico is considered a continuation of the preceding Archaic pattern. Hundreds of shell mounds were constructed along the coasts of Sinaloa and Nayarit and contained stone implements from an Archaic-style toolkit. Some of these mounds were immense, covering areas in excess of 3,000 m^2. Their size, shape, and construction have suggested that they were actually examples of monumental architecture as opposed to simply trash middens.

Many questions about West Mexico as culture region remain, and its perception has been obscured by a dearth of investigations. This situation is changing and recent research is beginning to fill-in the blanks (Beekman 2000, 2010; Williams et al. 2005). The region (i.e., the Mexican states of Nayarit, Jalisco, Colima, Michoacán, and the southern parts of Sinaloa, Zacatecas, Guanajuato, and Querétaro) followed an atypical cultural trajectory compared to other parts of Mesoamerica (Foster and Gorenstein 2000). Differences in cultural manifestations may be attributable to different linguistic traditions (Otomanguean, Purépecha, and southern Uto-Aztecan) (Beekman 2010). Additionally, variations can be partially ascribed to regional climatic and environmental conditions that required alternative ways of materializing similar Mesoamerican ideological beliefs.

By c. 1300 BC, shaft tombs at El Opeño, Michoacán were constructed and were significantly different from burial practices in eastern Mesoamerica (Beekman 2000). Their creators and their motivations remain obscure as tomb construction coincided with volcanic activity that covered the tomb sites and obscured the associated residential. Recent interpretations, however, have related tomb construction and content to shared pan-Mesoamerican themes related to the underworld and ancestor veneration. Evidence suggestive of auto-sacrifice has been uncovered, as have ceramic figurines of individuals wearing attire used in the rubber ballgame. These are notable indications of a broader Mesoamerican tradition that included West Mexico. Contemporaneous with El Opeño was the Capacha archaeological culture, in the state of Colima (Williams et al. 2005). Here, the earliest ceramic horizon for the Jalisco-Colima-Nayarit area were uncovered and included "stirrup-spout" vessels that suggest similarities with items found among the Tlatilco culture of the central Mexican highlands.

There was a comparatively late transition to agriculture, possibly as a result of an extended dry phase in West Mexico during the Archaic period. Ceramic traditions also appear later and have been associated with northwestern South America (e.g., the use of resist and red-on-brown decoration along with exotic bottle forms) (Anawalt 1998). West Mexican ceramic elements were also shared with sites like Tlatilco, in the Basin of Mexico, whose pottery exhibits ties to both the east and west Mesoamerica. West Mexico's participation in long-distance acquisition networks also demonstrates the two-way movement of materials and ideas. Jade (jadeite) from Guatemala's Motagua River Valley, iron pyrite mirrors suggestive of those from Oaxaca, and marine shell from the Atlantic Coast illustrate the scope of these socioeconomic systems. Obsidian exchange indicates the mutual nature of these transactions (e.g., green obsidian from Pachuca, Hidalgo, in central Mexico is present in West Mexico, and the jet black obsidian from the Ucareo source in Michoacán has been uncovered as far east as the Pacific Coast of Chiapas).

The Southern Gulf Coast Lowlands and the San Lorenzo Olmec

At the beginning of the Early Formative period (c. 2000–1800 BC), the southern Gulf Coast lowlands of Veracruz and Tabasco were subjected to climatic change, natural hazards, and landscape transformation (e.g., hurricanes, El Niños, La Niñas, annual inundations, and seismic and volcanic activity). It was also a region of exceedingly fertile and abundant flora and fauna. Village farming had extended northward across the Isthmus of Tehuantepec from the Soconusco Coast of Chiapas and was readily adopted in the Gulf lowlands. These two regions shared similar environmental and ecological similarities.

The Olmec of the Southern Veracruz lowlands were one of only a handful of "pristine" complex societies or civilizations that developed anywhere in the world without previous archetypes upon which to model their social structure (Diehl 2004: 11–12). Early Formative period San Lorenzo (c. 1500–900 BC), located on and around a plateau overlooking the Coatzacoalcos River in Veracruz, was the only one of these antecedent societies to emerge in a forested, tropical, lowland environment. The sui generis development of social complexity among the inhabitants of the Southern Gulf Lowlands constitutes a test subject for the study of social theory, both as a model and as a tool for evaluation (Coe and Koontz 2013: 61–72). The uniqueness of their appearance and environmental circumscription, plus the legacy of their cultural traits that were adopted by subsequent Mesoamerican societies, makes investigation of their social maturation critical to archaeological theorists.

Evidence of sedentary occupation along the lowlands included a sequence of the earliest regional ceramic horizons. The initial Ojochí phase pottery (c. 1500–1350 BC) bore similarities to materials from the Mazatán region along the Soconusco Coast. The Ojochí, along with Bajío and Chicharras phase ceramics (c. 1350–1150 BC), have been uncovered at sites along the San Juan and the Coatzacoalcos Rivers (i.e., El Marquesillo, Cuatotolapan Viejo, Estero Rabón-San Isidro, and San Lorenzo) (Coe and Diehl 1980; Doering 2007: 249–252). Although each of these sites would eventually become socioeconomic centers in their own right, it was San Lorenzo that would become the most important Early Formative period site in Mesoamerica.

The Olmec of the Southern Gulf Coast lowlands is an archaeological culture that emerged around 1500 BC, in the swampy lowlands of Veracruz, Mexico, along the northern edge of the Isthmus of Tehuantepec (Arnold 2009; Coe and Koontz 2013). These Olmec are credited with being the first established complex society in Mesoamerica, and it was at the site of San Lorenzo that they first demonstrated a suite of features and characteristics that would have a profound impact on contemporaneous and subsequent Mesoamerican peoples. The nature and extent of that impact has long been an issue of debate (de Antropología 1942; Blomster et al. 2005; Cheetham and Blomster 2010; Neff et al. 2006a, b; Sharer et al. 2006; Sharer and Grove 1989; Stoltman et al. 2005). Whatever one's position regarding the role of the San Lorenzo Olmec in the social development and ideological trajectory of Mesoamerica, their cultural, artistic, and monumental features that are demonstrated in the archaeological record are prodigious when compared to any other Early Formative period settlement.

Prior to around 1400 BC, San Lorenzo was a 20 hectare, egalitarian village located atop a 50 m high plateau adjacent to the Coatzacoalcos River in southeastern Veracruz. By 1100 BC, the village had evolved into, arguably, a state-level society and grown to at least 500 hectare (1,235 acres) with an estimated population of 10,000 and an additional 20,000–40,000 people living in the contiguous region (Clark 2004). The plateau had become a major urban center of political, economic, and religious power that headed a four-tiered settlement hierarchy. To demonstrate and support their claim to leadership, the elite controlled extensive interregional trade and acquisition networks, corps of highly skilled craftspeople, and a symbolic monumental art form that would become synonymous with their archaeological name (Benson and de la Fuente

1996; Cyphers 1997; de la Fuente 1992, 2000; Symonds 2000; Vega 2007). But for all its impressive and significant achievements, by the end of the Early Formative period, San Lorenzo would decline to relative insignificance.

Some 15 km southeast of San Lorenzo lies the site of El Manatí, an anaerobic spring used for the ritual deposition of offerings that included of wooden sculptures, rubber balls, jade celts, and other items, including infant burials (Ortíz and Rodríguez 2000; Rodríguez and Ortíz 1997). The offerings were deposited in three discrete phases: Manatí A (c. 1700–1500 BC); Manatí B (c. 1500–1400 BC); Manatí C (c. 1400–1200 BC), and each contained information regarding Olmec ritual practices during the Early Formative period (Ortíz and Rodríguez 1993). Several artifacts types are of particular note. Rubber balls used in the Mesoamerican ballgame were recovered from the Manatí A deposit making them the earliest examples known in Mesoamerica and were contemporaneous with the ballcourt uncovered in Paso de la Amada (see section "The Soconusco Coast" above). Numerous celts made of jade from the distant Motagua River Valley of Guatemala were also recovered from this initial deposit. The fact that these celts were exceedingly well made and extraordinarily highly polished suggests that the production and veneration of jade objects was a deeply rooted tradition that extends earlier in Mesoamerican history.

The Central Mexico Highlands

This region of Mesoamerica includes the modern Mexican states of Tlaxcala, Morelos, southern Hidalgo, central Puebla, and the Federal District (Mexico City). From a number of perspectives (e.g., geographic, geologic, and environmental), the region stands as a natural interface of the sociopolitical and economic traditions between east and west Mesoamerica. "People, goods, and ideas passed from one side to the other, and thus it holds many keys for our understanding of emerging social complexity in Mesoamerica . . .[and] the variation and dynamism of interregional interaction, including the formation of regional traditions, exchange systems, and foreign influence" are readily apparent (Plunket and Uruñuela 2012: 1).

The Central Highlands are also positioned to the north and south of Mexico's Neovolcanic Axis, which creates a geographic barrier to the opposing regions. At the same time, the broad deep valleys offer areas for the concentration of increasing populations in environmentally and ecologically productive zones. The presence of various natural resources were an attraction to external societies to the east and west, and thus facilitated long-distance interactions that enhanced the sociopolitical and economic development in the Highlands. Social inequality is evident, not only in the larger major center but also in the smaller villages and hamlets, where qualitative and quantitative differences in residential and burial goods mark the social structure (Carballo 2009; Uruñuela and Plunket 2002).

Generalized ceramic chronologies and reconstructions of the Preclassic period culture history in the Central Highlands were based on early twentieth century excavations at Tlatilco, Tlapacoya, and other sites in the Basin of Mexico (Gamio 1921; Vaillant 1930, 1931, 1935). More recent research, however, has revised many of the earlier assertions, finding sociopolitical differences to be more a factor of chronology as opposed to arrival of foreign elites (Niederberger-Betton 1987; Niederberger 1976; Tolstoy and Paradis 1970).

In Morelos, sedentary farming villages of 100–200 inhabitants were scattered across the Amatzinac Valley bottomlands during the Amate phase (c. 1500–1100 BC). During the Barranca phase (c. 1100–700 BC), the site of Chalcatzingo began to grow and emerge as a civic-ceremonial center that would reach its peak in the ensuing Middle Formative period (Grove 1987, 2008). The beginnings of landscape modification and architectural constructions at the site were coeval with its participation in what is referred to as the Tlatilco culture that developed between 1250 and 800 BC.

The Tlatilco culture has typically been closely associated with the Basin of Mexico and the sites such as Tlatilco, Tlapacoya, El Arbolillo, Zacatenco, Ticomán, and Cuicuilco and Coapexco, but recent research suggest its origins may actually be to the south, in the Morelos region

(Grove 2007). Ceramic connections with groups from West Mexico have also been observed (Williams 2004). During the period, stratified social structures corresponded to more elaborate settlement patterns and a substantial escalation in long-distance exchange that may account for a degree of the Gulf Coast Olmec art style present within the artifact assemblages.

The Maya Regions

During the Early Formative period, small, widely dispersed, densely populated villages participated in a mixed economy of hunting, gathering, and farming in the regions where the Maya civilization would later flourish. The inhabitants were perhaps Maya speakers, and they dotted the landscape of much of southeastern Mesoamerica. In the region, "The Early Preclassic begins in the Soconusco c. 1800 BC, and is marked by profound changes settlements patterns, subsistence, technology, and society" (Coe and Houston 2015: 49). Though the inhabitants of the Pacific Coasts, which included Chiapas, Guatemala, and El Salvador, were not Maya speakers, they would have substantial effects on the Maya peoples to the north, in the highlands and lowlands. It would not be until the opening centuries of the Middle Formative period that Mayas centers in the northern Petén region of Guatemala would begin to develop the sociopolitical foundations that would support and facilitate the eventual emergence of the Classic Maya (Inomata et al. 2013).

The Middle Formative Period (c. 1000–400 BC)

"The Middle Formative period. . .across Mesoamerica was qualitatively different from what preceded it" (Grove 2007: 220). Momentous socioeconomic, political, and ideological transitions that occurred during the Early Formative period laid the foundation upon which Mesoamerica would grow to become a distinct culture area. During the Middle Formative, the transition to settled life and expanding populations occurred throughout Mesoamerica. Although cultural regionalism increased with small villages coalescing into urban centers, an Olmec presence was still widely apparent. Monumental stone carvings, considered to be in the La Venta Olmec style, were erected at important trade centers and along communication routes. Ceramic industries intensified and new techniques were developed. The neckless jars (tecomates), common in the Early Formative Period, were replaced by a more durable pottery decorated with incised lines, frequently referred to as double-line break (see Tolstoy et al. 1977: 98).

Materials and ideas flowed in multiple directions between centers, and fundamental social, political, and economic transformations were accelerating across all of Mesoamerica; changes that would profoundly affect all future Mesoamerican societies. The scope and scale of interaction was amplified as populations increased rapidly and less desirable agricultural regions were settled out of necessity. Local chiefdoms proliferated along with complex sociopolitical alliances, exchange networks, and increased competition for natural resources and exotic products.

The Middle Formative period upsurge was led by a growing elite class that needed to communicate their status and affirm their right to rule. The new elites used their wealth and power to define their social identities through display of material possessions and public expressions of power. A rapid expansion in the demand for exotic goods and materials imposed changes to the structure and content of rapidly evolving interregional trade and exchange networks. Correspondences in the material demonstration of public identities suggest these leaders participated, to varying degrees, in an interaction sphere that carried a suite of shared economic, political, symbolic, and ideological concepts (Joyce and Grove 1999: 12). Results of this participation allowed the expression of status or corporate membership that differentiated individuals or factions from the rest of society while, at the same time, confirming the community's position within a pan-Mesoamerican system that was recognizable to distant peers.

The degree of similarity in the materialization and expression of power, wealth, and authority among emergent elite across Mesoamerica was remarkable, so much so that differences were a matter of scale and extent, not content. Because of this high level of correspondence, the collective manifestation of these expressions by the elite of a

community is referred to here as the Middle Formative Paradigm. Diagnostic elements of the paradigm included: designed architectural complexes (e.g., pyramids, plazas, special use structures, and ballcourts); water management systems; iconic ceramic vessels and figurines; high-status burials and ritual deposits; narrative bas-relief stone sculpture; and long-distance acquisition of exotic items, luxury goods, and resources (i.e., obsidian, jade, greenstone, marine shell, and iron ore). The Gulf Coast Olmec tradition was carried on at La Venta, in modern day western Tabasco. The Zapotec culture arose at Monte Alban in the Valley of Oaxaca, and multi-ethnic groups surged at Teotihuacan in the Valley of Mexico. The Maya civilization grew and proliferated across much of Guatemala, Belize, the Yucatán Peninsula and western Honduras. All these societies participated, to some degree, in the Middle Formative Paradigm.

Population growth was a major factor in numerous transformational processes and necessitated expanded agricultural activities that played a significant role in their development. Maize has been acknowledged as the primary agricultural product in Mesoamerica (Staller et al. 2009). Although there is evidence for the cultivation of maize as far back as 5000–7000 BC (e.g., pollen, plant remains, land clearing, and ground stone implements), direct evidence for its consumption as a dietary staple (i.e., stable isotope analysis of bone collagen, bone apatite, and tooth enamel) is not present until around 1000 BC (van der Warker 2006), precisely at the time of the population increase across Mesoamerica. Perhaps an underlying factor that propelled the demographic upsurge was the process of "nixtamalization," a maize preparation practice that has a number of significant benefits, possibly the greatest of which is the substantial increase in its nutritional value. Nixtamalized maize was so superior to the unprocessed type that without it some believe Mesoamerican civilization would have not progressed beyond the village level (Coe and Houston 2015: 49; Coe 1994).

Chiefdoms were the primary forms of social organization in Middle Formative period Mesoamerica; but they were relatively unstable, inclined to cycles of fragmentation, renewal, and expansion. The chiefly or elite ruling class was usually lineage-based, and an individual's role or social status within the chiefdom was generally determined by kinship. Middle Formative period chiefdom societies changed rapidly along with their power and prominence and can be better understood at a regional perspective.

The Pacific Coast

The southeastern terminus of Preclassic Mesoamerica was the Ahuachapán region of El Salvador where, during the Early Formative period, settlement consisted of modest farming villages. During the early Middle Formative period (c. 900–650 BC), Chalchuapa developed into a major trade colony, possibly as a result of interaction with the Southern Gulf Coast La Venta Olmec or groups from Morelos in the Central Mexico Highlands. At El Trapiche, a northern portion of the settlement, construction of a massive 20 m high platform took place, and at Las Victorias, the site grew into a leading political and religious center containing a massive boulder carved with multiple Olmec-style figures.

Approximately 700 km along the Pacific coast to the northwest, at the southern terminus of the Isthmus of Tehuantepec, was the site of Laguna Zope. Between 800 and 400 BC, Laguna Zope was a major trade center that specialized in the export of locally collected marine shell as well as acting as a redistribution point for materials originating in the Guatemala highlands (e.g., obsidian and jade). The inter-coastal waterway and riverine system along the Pacific coast between El Salvador and Oaxaca provided an almost unbroken stretch of flat water for the transport of goods and materials, a system that was actively maintained up to the beginning of the twentieth century. Adjoining this route were numerous sites that contain carved stone monuments that share common content and artistic canons associated with the major Southern Gulf Coast Olmec center of La Venta (Clark and Pye 2000).

Following the decline of sites in the Mazatán region of the Soconusco Coast, La Blanca, in westernmost coastal Guatemala (c. 900–600 BC) became one of Mesoamerica's largest Middle

Formative period sites and contained one of the earliest examples of the Mesoamerican temple pyramid and, at 25 m, the tallest on the Pacific Lowlands. La Blanca also exhibited one of the earliest examples of the quatrefoil shape, an iconographic feature that represented a portal to the underworld (Love and Guernsey 2007). Around 600 BC, the nearby site of Ujuxte would replace La Blanca as the dominant regional center. Several other sites along the Pacific coastal plains and adjoining piedmont (e.g., Izapa, Takalik Abaj, and Chocola) were developing population centers that would flourish in the Late Formative period (Love 2007).

Highland Guatemala

Small farming villages occupied many of the highland valleys of Guatemala during the Early Formative period. The appearance of Arevalo phase ceramics (c. 1200–1000 BC) at the settlement of Kaminaljuyú, located in present-day Guatemala City, was the first evidence of occupation that would last through the Late Classic (c. AD 900). During the Middle Formative period, Kaminaljuyú demonstrated considerable social complexity as it evolved into an administrative center thought to control the vast El Chayal obsidian source and the jade supply along the Motagua River Valley. The La Venta Olmecs were major importers of these commodities, and a trail of these materials follows a key riverine transport system between the Guatemalan highlands and the Gulf Coast that included such sites as La Libertad, Chiapa de Corzo, San Isidro, and others in Chiapas (Lowe 1981; Pye and Clark 2006).

During the Las Charcas to Providencia phases at Kaminaljuyú (c. 100–400 BC), population grew and all the elements of the Middle Formative Paradigm appeared. These factors indicate a centralization of authority by the settlement's elite leaders as they built the highland polity into a dominant socioeconomic capital. Sacrificial victims and captives become apparent on sculptures and burials indicate status differentiation. Similar events took place in the nearby Salama Valley, albeit to a lesser scale, as elites emerged and adhered to the Middle Formative period model.

Guerrero

The mountainous regions of Guerrero have produced evidence (e.g., carved greenstone objects, monumental stone sculpture, and cave paintings) that suggests a significant connection to the Southern Gulf Coast Olmec. Teopantecuanitlán, an important regional site that demonstrates this connection, was initially occupied around 1400 BC and reached its height in population and social complexity around c. 1000–800 BC (Martínez Donjuán 1996). Various lines of evidence demonstrate that the leaders were adherents to the Middle Formative Paradigm and participants in an interregional exchange network that included the Pacific coast, the Central Mexico highlands, Chalcatzingo in Morelos, the Southern Gulf Coast, and potentially the distant Maya lowlands. Acquisition of imported marine shell and obsidian from a variety of distant source provided materials for the production of luxury goods.

The presence of ceremonial architecture, water management systems, monumental stone sculpture, and Olmec-style ceramic wares demonstrated affinities with the Gulf Coast Olmec (Martínez Donjuán 2010; Reilly 2000). The corbelled arch or vault architectural feature is so closely associated with the Maya that it is called a Mayan arch. Yet, it was at Teopantecuanitlán that this architectural feature was first utilized in Mesoamerica and raises the question as to how and why this distinctive characteristic may have made its way to the Maya lowlands.

Paintings in the Juxtlahuaca Cave and Oxtotitlán rock shelter are two further examples of art and iconography that have been associated with the Olmec art style (Grove 1970). These sites are in remote canyons and not related to any major settlement; yet they are well developed in their execution, suggesting an established tradition. Mural painting is not common in the Middle Formative period, but the theme, content, and chronology have been associated with the Southern Gulf Coast and its symbolism and portraiture.

The Valley of Oaxaca

The settlement of San José Mogote, in the Valley of Oaxaca, was established in the Early Formative period (c. 1400 BC) and represents one of the

region's first permanent agricultural villages and among the first to use pottery (Flannery 1968). The site has been considered the originator of a number of significant sociocultural and political features (e.g., initial appearance of public architectural structures, earliest hieroglyphic writing, and institutionalized lineages). San José Mogote played a major, long-term role in the Valley of Oaxaca's sociopolitical development and was clearly the precursor to the Late Formative period civic-ceremonial center of Monte Albán.

Recent analyses have tempered some of the original claims about San José Mogote, however (Clark 2004; Pool 2007: 198–205; Rosenswig 2010). Nevertheless, near the end of the Middle Formative period, the Zapotec people were implementing artificially terraced hillsides and canal irrigation techniques. Evidence of increasing conflict, captive sacrifice, and defensive fortifications has been attributed to aggressive competition for limited resources of the valley. These factors may have been the reason for the rapid ascension of Monte Albán at the strategic, defensive hilltop location at the intersection of the three branches of the valley.

West Mexico

Information regarding West Mexico's socioeconomic and localized centralization of political control during the Middle Formative period has been derived primarily from evidence recovered from mortuary features. The shaft tomb tradition of this region that began around 1300 BC and continued into the Middle Formative period is thought to be lineage-related and contained sumptuous imported objects that demonstrated the status and wealth of the interred families. These practices expanded across the region as wealth and status appears to have been a result of membership in corporate social groups.

Based on the funerary objects, it is clear that West Mexico increased its participation in multiple long-distance interaction spheres. These systems not only involved contact with the most distant parts of Mesoamerica (e.g., jade from the Motagua Valley of Guatemala, Pacific and Atlantic Coast marine shell, Oaxaca iron pyrite mirrors, and central Mexican obsidian) but also interaction with northern Mexico and New Mexico was demonstrated by the presence of turquoise. At the same time, local materials and technologies were being circulated to other regions. Obsidian from Michoacán's Ucareo source is found in the Basin of Mexico, the Oaxaca Valley, and the Gulf Coast. A unique style of circular mounded architecture that originated in West Mexico is seen at distant regions such as Cuicuilco, in the Basin of Mexico, and Capacha and El Opeño ceramic types are found at the contemporaneous site of Tlatilco.

There are two factors that should be noted about West Mexico. First is that evidence of the Olmec art style in the region is visibly absent at this time. Second is that the region continued to display ancient associations with northwestern South America, specifically Ecuador (Callaghan 2003; Townsend 1998). The number and type of associations and the supporting evidence (e.g., archaeological, biological, technical, metallurgical, and ethnohistoric) suggest the possibility of recurrent contact be considered when evaluating the development and trajectory of West Mexican culture. Additionally, new archaeological evidence and lines of inquiry are expanding our knowledge of West Mexico (Williams et al. 2005).

The Southern Gulf Coast Lowlands and the La Venta Olmec

The final phase of the Olmec phenomenon occurred during the Middle Formative period with La Venta taking up the cultural mantle left by San Lorenzo's relatively rapid and not fully understood decline (Pool 2007). The capital of La Venta was located within a dynamic Tonalá riverine system in present-day Tabasco, and it was a leading example of complex society in Middle Formative period Mesoamerica (Diehl 1990, 2004). The city's elite imported goods and materials from across Mesoamerica and established the benchmarks for the materialization of the Middle Formative Paradigm (e.g., jade and greenstone objects, planned civic-ceremonial architecture and water management systems, monumental stone carving, and "massive offerings"). It disseminated ideological and artistic canons directly related to maize and possibly distributing

agricultural or technological techniques (Reilly 1995; Taube 2000).

Widely dispersed populations shifted into more nuclear centers across the alluvial lowlands of the Southern Gulf Coast, possibly in response to volcanic activity in the Tuxtla Mountains and regional climatic changes (Santley et al. 2000). Along the middle San Juan River, continuation of El Marquesillo's occupation was evident in its architectural and ceramic development (Doering 2007). El Viejón, on the Gulf Coast, may have operated as a commercial control station for La Venta and was the northernmost site with direct Olmec connections (Wilkerson 1981). Olmec-related jade and portable art items have been uncovered around the El Pital region of north-central Veracruz, and Middle Formative period communities around the Pánuco region expanded the northern boundaries of Mesoamerica along the Gulf Coast. Smaller, less-concentrated populations may account for the slower development of social complexity in the region. Tres Zapotes, east of the Papaloapan River, produced monumental stone sculpture and demonstrated a chiefdom-level society that would continue into the epi-Olmec period (Pool 2000, 2005).

The Central Mexico Highlands

During the Barranca phase at the site of Chalcatzingo, in Morelos (c. 1100–700 BC), the modest public architecture of the Early Formative period was replaced by a series of modified terraces that transformed the earlier village and added an elite house compound for the chiefly lineage (Guillén and Grove 1987; Grove 2008). A series of bas-relief narratives were carved on stone boulders and outcrops during the Cantera phase (c. 700–500 BC) and were directionally distributed with ideological representations to the south and depictions of political rulership placed in the elite residential area to the north. Although evidence suggests a small population, the presence of monumental architecture, exotic elite goods, and a large carved stone corpus, the settlement represents a major regional center with substantial connections to the Gulf Coast, Guerrero, and the Pacific Coast (Grove 1987).

In the Basin of Mexico, the development of political and ideological complexity has been seen as trailing behind those of southern Mexico. Settlement along the southern portions of the basin was limited to small villages occupied by members of the Tlatilco culture (e.g., El Arbolillo and Zacatenco) (Sanders et al. 1979). In the site of Tlatilco, evidence of Early Formative Olmec influence underwent a significant change around 1000 BC. Iconographic and stylistic modifications presented a more local type of expression that may represent modifications in ideological practices, perhaps as a result of the decline of San Lorenzo (Niederberger 2000). By c. 700 BC, Cuicuilco became a dominant center in the Valley of Mexico, where attributes of the Tlatilco culture were no longer evident (Gonzalez et al. 2000). Cuicuilco would prevail as the valley's major civic-ceremonial center, but Cuautlalpan and Chimalhuacan were also large settlements along the southern and eastern shores of Lake Texcoco. These autonomous centers shared the landscape until around 150 BC, when Teotihuacan would rise to become the largest urban center in Mesoamerica. The development of rank societies would spread sporadically across the valley and into the neighboring areas of Tlaxcala and Puebla.

The Maya Region

Occupied since at least c. 1400 BC, the Maya region, including the Yucatán Peninsula, had more or less followed the same socioeconomic and political trajectory as much of the rest of Mesoamerica. Small, dispersed agricultural villages of 100–200 inhabitants dotted the lowland landscape. That scenario began to change when exotic objects and elite luxury items were imported around 900–750 BC, at sites like Seibal and Altar de Sacrificios (Estrada-Belli 2011; Inomata et al. 2013). The increasing appearance of prestige goods suggests an expansion of extensive trade networks. The construction of canal and irrigation systems of increasing complexity and scale required substantial coordination of labor and management. At the site of Nakbe, in the Mirador Basin of the northern Guatemala Petén, production of monumental architecture began

c. 600–350 BC (Hansen 2005). Following earlier Southern Gulf Coast traditions, standing carved stone monuments (stelae) were placed atop platform structures c. 500–300 BC. An extensive network of raised, paved causeways (sacbeob) would be built to link emerging settlements within the basin, including El Mirador, El Tintal, and Wakna, that would, during the following Late Formative period, alter the political geography of the southeastern Mesoamerica (Aguilar et al. 2008).

During the Swasey phase (c. 1200–900 BC), at the site of Cuello in Belize, the establishment of maize agriculture and the introduction of ceramic technology were evident (Sharer and Traxler 2006). In the following Bladen phase (c. 900–650 BC), ceramic associations expanded to the lowlands around the Pasíon River basin, and obsidian and jade were imported from southern Guatemala. Elite wealth and ascribed status were demonstrated in residential contexts and child burials. Mayas from settlements in the southern Petén migrated north along the west coast of the Yucatán Peninsula setting up permanent settlements at Dzibilchaltún, Dzibilnocac, and Komchen. Later incursions by Maya from Belize and the eastern Petén moved northward along the eastern coast of the peninsula (Estrada-Belli 2011).

Southeast Mesoamerica

The eastern boundaries of Mesoamerica during the Preclassic period extended roughly from the Bay of Tela, on the Caribbean Coast of Honduras, south to the Gulf of Fonseca on El Salvador's Pacific Coast. In the Ulua River Valley of Honduras, the settlement at Puerto Escondido contained an exceptionally large mound structure possibly for civic functions (Joyce 2004). At Playa de los Muertos, child burials contained jade and other objects, while an adult burial at the site contained only unadorned skeletal remains, signs that demonstrate ascribed status. At both Honduran sites, artifacts included Olmec-related styles and motifs. Further to the south, Los Naranjos and Yarumela each were anchored by large 20 m high mound structures. Their location along a well-traveled communication route and the presence of marine shell, jade, nonlocal obsidian, exotic ceramics, and other luxury commodities suggest these settlements were trade outposts for the movement of Olmec-related materials.

The Late Formative Period (C. 300 BC–AD 250)

A number of significant socioeconomic and political episodes occurred across Mesoamerica during the Late Formative period. The cultural vacuum created by the demise of the Olmec at La Venta, and with it the Southern Gulf Coast Olmec civilization, was filled by a variety of emergent successors. Major cities, states, and culture groups arose in the Valley of Oaxaca, the Mirador Basin, the Guatemala Highlands, and at the urban colossus of Teotihuacán in the Valley of Mexico. Regional hegemony and local cultural integration became the new model for sociopolitical structures, and elite rulers put greater social distance between themselves and their constituents, and conflict became commonplace across Mesoamerica.

Generalized traits continued to permeate much of Mesoamerica. Shared characteristics involved similarities in ceramic horizons, the construction of temple-pyramids, and common burial practices. Widespread, intensive agricultural practices (e.g., terracing, irrigation, and raised-fields) were developed and implemented to provide the increased subsistence production needed to support rapidly growing populations. The ways in which Middle Formative period elite leaders distinguished themselves from their constituents (e.g., acquisition of exotic and luxury goods, conducting labor intensive public works projects, and commission monumental stone sculpture) were expanded.

Religious and ideological traditions were refined, reinforced, and facilitated through the use of emergent writing systems. Recent research into Mesoamerica epigraphy and iconography demonstrates that the Late Formative period was a pivotal time in the evolution of writing and calendric systems (Justeson and Kaufman 1993; Kaufman and Justeson 2009). Embedded on sculpted monuments were messages that "articulated political ideologies and complex cosmological themes, and formed a shared language of power that was employed by rulers in a Late

Preclassic communication sphere" (Guernsey 2006: 1). Early evidence of writing occurred in the Valley of Oaxaca, Chiapas, Guatemala, and Veracruz.

The Pacific Coast

The ethnic affiliations and political relationships along the Pacific Coast during the Late Formative period remain uncertain as numerous, diverse groups occupied the region. A series of sites: Izapa, in the west; El Ujuxte, Takalik Abaj, Chocola, and Kaminaljuyú, in the east had the unusual distinction of all being major centers, located within a 40–60 km distance from one another, that experienced their phases of florescence at the same time (Love 2007). Izapa is a large center near modern-day Tapachula, Chiapas, that contains multiple complexes of earthen mounds and platforms, but its notoriety stems from the large number of carved stone monuments that depict scenes of rulers, deities, and creation myths in an iconic language of power and authority (Guernsey 2006; Kapplemen 2001). The Izapan civilization has been heralded as a cultural intermediary between the earlier Olmec and later Maya and, although this hypothesis has some support, it is an oversimplification of the evidence (Rosenswig 2010).

The major Middle Formative period capital of La Blanca was replaced by El Ujuxte, a Mixe-Zoquean center with a three-tiered settlement hierarchy that may have withstood the regional Maya expansion (Love 2007). The site of Takalik Abaj, east of Izapa, on the Pacific Piedmont of Guatemala, contains one of the most eclectic assemblages of monumental stone sculpture in all of Mesoamerica, including examples of regional Pacific coast and piedmont styles as well as Southern Gulf Coast Olmec, Izapan, and early Maya styles. This diversity may be attributed to the settlement's location at the boundaries of multiple linguistic and cultural areas. Sculptural styles identified as Olmec or Olmecoid, Izapan, Pacific Coast, and Maya. Chocola, located just to the east of Takalik Abaj, shares some traits with its neighbor, such as cacao production and water management systems. Its cultural affiliations, however, appear more closely tied to the major settlement of Kaminaljuyú, on the western edge of present-day Guatemala City.

The Valley of Oaxaca

The establishment of Monte Albán, in a previously uninhabited area at the center of the valley, around 500 BC, represented a monumental transformation in the regional sociopolitical structure and settlement patterning (Marcus and Flannery 1996). Populations from various settlements across the valley were shifted to the site, which was defensively positioned on an elevated plateau 400 m above the valley floor (Spencer and Redmond 2001). Architectural complexes built on the leveled mountain top appear to have been constructed according to a master plan. They contained a formal ballcourt, plazas, patios, temple-pyramids, and a possible astronomical observatory, and in the Mesoamerican tradition, earlier structures were later built over. Cultural influences from southeastern Mexico were demonstrated in the form of ceramic traditions, and iconographic representations of vanquished captives (danzantes) and Zapotec place name glyphs were incorporated into the designs of structures and public areas. Issues of access to water and agricultural lands would have required new, more stringent methods for the control of labor and management of resources.

West Mexico

The Late Formative period in West Mexico is characterized by rapid population growth and attempts made to consolidate political power at regional centers (Beekman 2000). There was also expansion by farming groups into previously unoccupied areas including the Bajío region, north of the Lerma River Valley. This movement extended the northern boundaries of the Mesoamerican culture area. Associated with this expansion was the Chupícuaro culture, named after the southeastern Guanajuato site where high-quality ceramics were produced between 600 and 100 BC. Recently, shaft tombs were uncovered at Chupícuaro sites that contained objects similar to those found across the western highlands (e.g., solid and hollow human figurines, shell imported from the Pacific and Gulf Coasts). Although these

similarities demonstrate the long-term continuity of this cultural trait across much of West Mexico, differences in the richness of the tombs' contents and their proximity to public architecture imply social inequality (Beekman 2010).

The shaft tomb tradition of West Mexico has its antecedents in the Early Formative period and it continued to expand throughout the Preclassic period. The rise of the Teuchitlán tradition (c. 200 BC–AD 200) is considered an extension of the earlier shaft tomb tradition of West Mexico. Notable for its new architectural style of circular central plazas and conical step pyramids that were regulated by the elite. Larger sites, such as Los Guachimontones, became the model with fortified, defensive sites surrounding the major centers, suggesting political tensions.

The Southern Gulf Coast Lowlands

The Olmec phenomenon had come to an end by the Late Formative period, and significant changes occurred throughout the region. Tres Zapotes, which exhibited some remnants of the ancient Olmec society, underwent substantial transformation (Wade 2017b), a portion of which has been linked to the Izapan culture on the Pacific Coast of Chiapas. A primary example of this connection is Stela C, an Izapa-style mask that was carved into one side of the stone monument, while the other side contained one of the earliest Long Count dates of 31 BC. Such an early date has raised ideas that the Long Count calendric system, which had been considered a Maya innovation, was established in the Late Formative by epi-Olmec peoples outside the Maya region (Pool 2000).

Elsewhere, there was acceleration in development of cultural complexity that expanded along the Gulf Coast from the Tuxtla Mountains to the Panuco River area. Cerro de las Mesas was established as a regional center in the Mixtequilla area of the Papaloapan River basin, just to the west of what was the Olmec heartland, beginning around 600 BC. To the north, the Remojadas culture began its emergence. A major feature in the region was the appearance of an Epi-Olmec or Isthmian hieroglyphic script written in the Zoquean language that is still spoken in the region. The most renowned example is the La Mojarra Stela, a four-ton limestone slab that holds some 535 glyphs. A tentative decipherment of the text suggests an account of warfare, ritual performance, and celestial events that document a ruler's rise to power (Justeson and Kaufman 1993). This format would become the widely accepted method of propagandizing by rulers throughout Mesoamerica in the following Classic period.

The Central Mexico Highlands

Cuicuilco continued as one of the largest and most important settlements into the Late Formative period. Possibly the earliest stone pyramid on the Mexican plateau was constructed at the site. The circular structure is thought to be dedicated to the famed of Mesoamerican deity Quetzalcóatl. The site was abandoned around 300–400 AD, when a lava flow from the nearby Xitle Volcano (Gonzalez et al. 2000; Siebe 2000). The exodus from the site probably led to immigration to Teotihuacán at the north end of the Basin.

Midway through the Late Formative period (c. 200 BC), the site of Teotihuacan was established on a 2,000 m high plateau in the northeastern part of the Basin of Mexico, and by AD 200, it had become the largest (20 km^2), most populated (80,000–100,000 residents), and most dominant city in Mesoamerica (Carballo et al. 2007; Headrick 2007; Millon 1981). Within a few centuries, the influence of Teotihuacan would be felt across the majority of Mesoamerica. The early stages of its development are not well understood, but there is little question its leaders were intent on constructing more than a center of commerce. Monumental construction was initiated along a mile-long "Avenue of the Dead," immigration from distant locales ensued, burgeoning agricultural production and intensive utilization of natural resources took place, technological innovations emerged, and new religious institutions and sociopolitical organizations were established. Much of the city's power appears to have been derived from the ideological materialization of inspirational deities and cosmology. The center's supremacy was supported through

intensive production and export of goods and materials, and a consequent dissemination of its ideology.

Guerrero

Most of the activity in Guerrero during the Late Formative period occurred around the Balsas River drainage. Middle Formative period, Olmec-related sites at Teopantecuanitlán, Oxtotilán, Amuco, and Juxtlahuaca demonstrated the regions significance to earlier cultural development (Coe and Koontz 2013). During the Late Formative period, the region continued to act as a cultural interface that included the Mezcala and Chumbícuaro cultures and shaft tombs of the West Mexico tradition were found in Tepalcatepec Valley. Recently, at site of Cuetlajuchitlán (c. 600 BC–AD 200), a well-developed series of interrelated architectural complexes was uncovered (Manzanilla López et al. 2006). The urban design included civic-ceremonial structures, water supply systems, and sunken patios. Materials from across Mesoamerica were present at the site demonstrating it served as a major trading center that facilitated the movement of goods to and from the Central Mexican highlands to the Pacific Coast.

The Maya Region

Between 600 BC and AD 100, the Mirador Basin in the northern area of the Guatemalan Petén was the epicenter of the development of Maya social complexity with the concurrent emergence of sites like Nakbe, El Mirador, El Tintal, and Wakna (Clark and Hansen 2001; Aguilar et al. 2008). These sites were of a spatial magnitude that had never been seen previously anywhere in Mesoamerica and would not be seen again in the Maya region, even during the Maya "Golden Age" of the Classic period. Population in the basin exceeded 100,000 and the Danta Complex at El Mirador was the tallest pre-Columbian structure in the New World. Tikal and Calakmul were contemporaneous centers that would become major rivals after the settlements in the Mirador Basin declined at the end of the Late Formative period.

The widespread use of hieroglyphic writing across the area provided an exceptional dated record of Maya kings and their exploits. Along the Pacific coast and piedmont (e.g., Chalchuapa, El Baúl, Chocola, and Takalik Abaj) early Maya inscriptions and depictions of rulers are predecessors of the rich burials and records at Kaminaljuyú (Doering and Collins 2008; Houston et al. 2005; Inomata et al. 2014; Valdés and Wright 2004). El Portón in the Salama Valley is transformed by a series of earthen terraces and platforms related to religious and political activities, and a large stone stela with a partially preserved glyphic text was ancestral to later Classic Maya forms. At these and other sites, evidence for the proliferation of warfare is clear. The expansion of trade connections and the consequent development of Maya sociopolitical complexity to lowland Maya sites are also accompanied by conflict. Adding to the competition is the widespread influence of Central Mexico's Teotihuacan, evident at sites like Kaminaljuyú, Tikal, and Copán. In addition to those already mentioned, settlements across the lowlands of the Petén and Yucatán Peninsula (e.g., Cuello, Cerros, and Blackmon Eddy in Belize; Calakmul, Becán, Loltun, San Bartolo, Cival, Uaxactun, Pomona, Komchen, and Dzibilchaltun, and countless others) provide the foundation for the subsequent flourishing of the Classic period Maya (Coe and Houston 2015; Saturno et al. 2006; Sharer and Traxler 2006).

Summary

The move toward sedentism intensified throughout the Preclassic period in Mesoamerica. Beginning in the Early Preclassic (c. 2000–1000 BC), the emergence of village life and developing agricultural practices produced larger populations that resulted in institutionalized social inequality. Surpluses provided the engine for the further development of long-distance exchange networks, and art and architecture became the preferred method of demonstrating elite individual and group identity. The Olmec of the Southern Gulf Coast lowlands emerged during the Early Preclassic at San Lorenzo. Arguably the earliest civilization Mesoamerica, the Olmec established many of the ideological and sociopolitical principles that would be carried on by subsequent Mesoamerican societies. A few regional centers that were interspersed across the landscape would reach a higher level

social complexity, while the spread of ranked societies across the rest of Mesoamerica would occur unevenly.

In the Middle Preclassic period, capital centers expanded in size and population. Monumental art and architecture reached new highpoints, and control and authority over labor and trade became entrenched. The second Gulf Coast Olmec capital of La Venta established artistic canons for iconographic representations that were followed across Mesoamerica to varying degrees. As the Olmec declined during the Middle Preclassic, societies in the highlands and the Maya lowlands arose to fill the socioeconomic and political void. The transition period from the Middle to Late Preclassic witnessed distinct regional ethnic styles. Large and small regional settlements moved toward centralized plazas with surrounding architectural structures, which were conducive to a greater emphasis on markets replete with local and long-distance goods and materials.

The stage was set for the blossoming of regional cultural centers across the expanding landscape of Mesoamerica during the Classic period. Highly developed societies led the move toward more complex political, intellectual, and metropolitan development. Monumental architecture and artistic creativity would reach their height of excellence, and social infrastructure that had emerged and matured during the Preclassic period would become foundational to the rise of the independent city–states of the Maya, and the great center of Teotihuacan would dominate the Valley of Mexico. Throughout Mesoamerica, transitory as well as enduring alliances were created that were comprised of principal capitals and vassal states. Monte Alban controlled the Valley of Oaxaca, the complex society of the Teuchitlán tradition emerged to influence the regions of Nayarit and Jalisco in West Mexico. Veracruz saw multiple cultures arise, major centers on the Pacific Coast waned, and the still murky Mezcala culture was established in Guerrero. The solid foundation that has been established during the Preclassic period facilitated the development of Golden Age of Mesoamerica.

Mesoamerica: Complex Society Development

William R. Fowler
Department of Anthropology, Vanderbilt University, Nashville, TN, USA

Introduction

Mesoamerica is primarily a cultural and linguistic concept useful to refer to groups of people who lived within a defined geographic region over a long period of time and who shared certain cultural and linguistic features and cultural practices, the most important of which are (1) a basic structuring economy, (2) beliefs about how the world works (cosmology) and practices related to those beliefs, and (3) material signs of stratification (Joyce 2004). The term refers geographically to the culture area that includes most of Mexico below the northern desert region and northern Central America minus the Caribbean lowlands of Honduras and Nicaragua to the east. Its geographic boundaries encompass the regions in which favorable climate and soils make maize agriculture feasible, and maize was in antiquity (and still is) the basis of the indigenous subsistence economy. Maize and other native cultigens such as squash, beans, and chili peppers were domesticated in Mesoamerica during the Archaic period, beginning about 5000 BCE (Acosta Ochoa 2017; Evans 2013: 88–89).

Definition

"Complex society" is defined here as social formations characterized by hereditary status-ranking differentiating elites and commoners, pervasive social inequality between these two broad social classes, and differential access to wealth and resources (both material and spiritual) (McGuire 1983; Fowler 1991). The phrase "development of complex society" is not necessarily limited to the earliest appearance or "pristine" cases of hereditary inequality, sometimes referred to "transegalitarian" societies because they are transitional from egalitarian to rank societies: political leadership surpasses the boundaries of kinship, acting further afield than the strictly local sphere and extending beyond the lifespan of the individual who exerts it, but neither institutionalized forms of power nor political centralization exists (Hayden 1995). Nevertheless, due to space limitations, this entry will focus on the earliest known archaeological evidence for the appearance of such societies.

Key Issues

By about 2000 BCE, the beginning of the Formative or Preclassic period, Mesoamerica was

inhabited by thousands of small, relatively homogeneous, egalitarian communities of full-time farmers, each consisting of perhaps 10–20 wattle-and-daub houses with thatched roofs and associated activity areas such as kitchens, midden deposits, and storage pits. Age, gender, and personal achievement constituted the dimensions of social differentiation. Agricultural tasks, craft production, and trading were organized at the household level. Some, but not necessarily all, ritual activities and interaction with outside groups may have been organized at the community level, but households and kin groups retained a high degree of autonomy. Leadership was based on achieved status, assumed by individuals with appropriate skills and personal qualities to specific activities and tasks.

Within a few centuries after 2000 BCE, a number of communities of considerable size and complexity – regional centers of economic, political, and religious power – appeared in various regions. At these centers, we see archaeological evidence for the emergence of complex society. These early hot spots of social complexity were considerably larger than most other contemporaneous settlements in their respective regions, and they possessed elite residential architecture ("chiefs' houses"), substantial ritual structures (elevated temple platforms), or both. Some featured public civic-ceremonial spaces such as plazas and ball courts.

The earliest development of political hierarchies in Mesoamerica, reflected in differences in mortuary furnishings, variation in residential form and construction, and tributary economies indicated by differential intrasite distributions of imported, exotic goods such as fine ceramics, mica and iron-ore mirrors, marine shells, obsidian, and greenstone, may be traced to this period. At this level of complexity, the household economy remains central in daily life, but institutional inequality fosters competition between hereditary elites who jockey for position and privilege. These individuals fulfill the roles of community political leaders and ritual specialists who reward cadre with gifts; manage communal labor; sponsor commensal activities; organize and direct interaction with other groups involving trade, tribute, and alliances; and organize and sponsor intergroup competition and violence.

Current Debates

Four decades ago, Kent V. Flannery (1976) influenced a generation of archaeologists to expect that such societal changes would result from gradual evolutionary trends resulting from the long-term effects of sedentary farming that developed in the Late Archaic period (3500–2000 BCE). The idea was that plant selection and improved diet led to population growth, fissioning of social units, and a general settling down in small, egalitarian villages throughout Mesoamerica. Some of these villages, because of differential access to critical resources, eventually became larger and more complex and developed new social institutions. They began to control more trade routes, engaged in increased social and economic exchange, and instituted formal political leadership. While very reasonable and well supported for its time, the gradualist village model of the origins of Mesoamerican social complexity did not anticipate the fact that some precocious centers with ranked society would begin their existence as full-blown, large villages with institutional inequality rather than small, egalitarian villages gradually moving in that direction.

Although many Mesoamerican regions have Initial Formative occupations dating to as early as 2000 BCE, none has the same archaeological evidence for early social complexity as the southeastern region. For more than 20 years, Mesoamericanists have suspected that the earliest development of complex society in the area may have occurred on the southeastern Pacific coastal plain and piedmont stretching from the Soconusco region of the Mexican state of Chiapas and down along the coast of the Central American republics of Guatemala, El Salvador, and Nicaragua (Fowler 1991). At the moment, the best data related to this issue come from the Mazatan zone of Soconusco where a detailed sequence and a number of early centers are known.

Examples

One such precocious center was the polity centered on Paso de la Amada, a large village site in the Mazatan zone of Soconusco, excavated by Michael Blake (1991) and John Clark (1991, 2004a, b). This ancient village, dating to 1650–1500 BCE (calibrated), appears to have been one of several regional centers of two-tiered settlement systems in the Mazatan zone. The core or ceremonial center of Paso de la Amada covered an area of approximately 40 ha, and the entire site covered 140 ha of dispersed construction (Clark 2004a: 54, 60), more than eight times the size of the next largest known center in the Mazatan zone (Rosenswig 2000: 427). Based on the criteria of size, the site could be considered a small town rather than a small village, but Clark and Blake do not make this claim.

The material culture of the Mazatan Early Formative centers features an array of symbolic goods that indicate social inequality such as ceramic figurines portraying obese males attired in ritual garb, wearing animal masks, and sporting round disks (iron-ore or mica mirrors?) on their chests or attached to a helmet or headdress, interpreted by Clark as depictions of shamanistic chiefs. At the El Vivero site, the osteological remains of a child, 11 years of age at death, were discovered. Grave goods interred with the child included a mirror fashioned of white mica mounted on a round sherd disk buried at the child's forehead region (possibly affixed to a helmet or headdress of perishable materials similar to those depicted in the figurines), clearly indicating ascribed social status. In addition, the child's body had been covered with red pigment, possibly another indication of high status.

Excavations of Mound 6 at Paso de la Amada revealed a sequence of at least nine superimposed platform construction levels of an aristocratic household (Clark 2004a: 56–57; Blake et al. 2006). The remains of these successive elite residences consisted of packed clay floors with postholes, concentrations of sherds and charcoal, bone fragments, trash pits, and occasional subfloor burials. The apsidal-shaped Structure 4 measured 10 by 22 m and was especially elaborate and well-constructed (Lesure and Blake 2002: Fig. 2). It is noteworthy that Mound 6 is the only one of several elite house platforms known in this large village that underwent sequential rebuilding; the others were abandoned in time. During the same period, three other elite residences at Paso de la Amada were built on smaller platforms (Mounds 4, 13, and 32), and approximately 40 small, non-elite residential mounds were built without platforms (Lesure 1997; Rosenswig 2000). These details and associated artifacts and features support the interpretation that Mound 6 was a chiefly residence which increased in relative wealth and status over the course of many generations, as inferred from superimposed building episodes. A symbolic transgenerational link with the past (social memory) is indicated by maintenance of the same shape and orientation of the house through successive rebuilding episodes. The architectural sequence of Mound 6 thus suggests a lineage of petty chiefs successfully consolidating power and passing their leadership to progeny in their household (Hill and Clark 2001: 332).

The rising fortunes of this household may have been connected with sporting and gaming activities. A monumental civic-ceremonial structure, Mound 7, located less than 200 m north of Mound 6 at Paso de la Amada, is regarded as the earliest known ball court and the largest construction known for its time in Mesoamerica (Evans 2013: 114). This is an earthen construction consisting of two parallel mounds with a central playing alley measuring 80 m long and 7 m wide. The flanking mounds are each 80 m long, 30 m wide, and 1.5 m high (Hill and Clark 2001: 333). Stratigraphic cross-dating indicates that construction of the ball court slightly predated the earliest of the sequential modifications of the Mound 6 houses, dated to about 1600 BCE (Blake et al. 1995). Hill and Clark (2001: 331) argue that location of the ball court in close proximity to an elite residence and its early date "constitute strong circumstantial evidence that its construction and/or use was important in and for the development of hereditary inequality and formal ascribed leadership." They highlight the close connection between sporting activity in the forging of community identity and the coalescence of leadership

roles around individual leaders. Drawing on Pierre Bourdieu's theory of practice, they argue that gaming activities and elite sponsorship of ball playing would have created an avenue for the accumulation of economic and social capital which would have contributed to the heritable power of an emerging chiefly lineage (Hill and Clark 2001: 341).

In their first formulation of a model of trans-egalitarianism at Paso de la Amada, Clark and Blake (1994) viewed the origins of hereditary village leadership as an accidental consequence of self-aggrandizing individuals pursuing advantage through feasting and competitive acts. They argued that the development of complex society in the Mazatan region was a long-term process involving "special historical and techno-environmental circumstances," the product of "self-interested competition among political actors vying for prestige or social esteem" (Clark and Blake 1994: 17). Hill and Clark (2001: 343) critique the aggrandizer model as overly materialist and political because it downplays the phenomenological component of cultural practices. In contrast, these are foregrounded in the practice-based interpretation of embodiment of ball game habitus related to community leadership based on manipulation and control of material and ideological resources, in turn fostering a sense of community identity (*communitas*), "largely an outgrowth of support for the village team and related activities" that crosscut lineage loyalties. Communitas implicated a titular community head and, combined with chronic disparities in social responsibilities and perquisites, created fertile ground for opportunistic elites to convert achieved leadership roles to heritable rulership.

Clark (2004a, b) argues that the large plazas and monumental buildings at Paso de la Amada were formally planned and laid out according to cosmological principles and using a measurement system of modular units that corresponded to numbers in later Mesoamerican calendar counts. The execution of such an ambitious scale of monumental construction would have required the mobilization of a significant collective labor project. Such a massive communal construction project would also have contributed to communitas through participation in inter-lineage activities, instilling a sense of shared ownership in the results of the project, and especially through a cosmologically charged statement of community identity that conferred founder status on the person or persons who organized and sponsored these activities (Clark 2004a: 61).

The last house of Mound 6 and the ball court of Mound 7 at Paso de la Amada fell into disuse at about 1350 BCE (calibrated), and the site itself was abandoned about a century later and never reoccupied (Clark 2004a: 54, 57).

Mesoamerica: Strengths and Weaknesses of the Current Classification

Astrid Runggaldier
University of Texas, Austin, TX, USA

Introduction

Mesoamerica is an analytical term that unifies several cultures of a particular region of the Americas. In this entry, a definition of Mesoamerica as an analytical term is presented in its historical context of development and use. A group of characteristic traits of several cultural traditions has historically been at the root of the term Mesoamerica, but the functionality of the term itself was meant to be as a heuristic device. Here, a commentary on its usefulness highlights both some advantages and disadvantages that resulted from grouping different historical trajectories into a single broad cultural realm. And, finally, while local academic disagreements renew debates on whether the term Mesoamerica has exhausted its

value, the strength of this term as a concept emerges best in cross-disciplinary and comparative contexts, providing a means of including Mesoamerican cultures in global discussions of complexity and world archaeology.

Definition

The term Mesoamerica is a concept that comprises the cultural phenomena of the indigenous world of Middle America. It is a framework of reference specifically devised to address cultural characteristics and boundaries, as opposed to geographical and political ones. Therefore, it is the cultural term that refers to a physical setting roughly encompassed between the river valleys of Sonora in northern Mexico and those of Honduras at the southern limits, comprising the modern nations of Mexico, Guatemala, Belize, Honduras, and El Salvador, with some of these only partially included. For example, the Maya archaeological site of Calakmul in the state of Campeche is politically in the nation of Mexico, geographically within North America, and culturally in Mesoamerica.

While the above example generates little scholarly issue, further north and south, the question of boundaries is at the heart of the sources of disagreement that have been problematic since the initial use of the term. Because the frame of reference is cultural, these boundaries cannot be drawn as hard and fixed lines; these are mobile and unstable cultural frontiers, and they vary with the frame of reference and with the temporal framework. Fluid frontiers represent cultural interaction spheres, so aspects of belonging and exclusion from what were traditionally defined as the "high civilizations" of Mesoamerica in contrast to the "lesser tribes" beyond it (Kirchhoff 1952: 19) have made for scientific, social, and political strife among scholars working in those areas. Most scholars who would refer to themselves as Mesoamericanists tend to work in the core, leaving the issue of boundaries somewhat unresolved.

Temporally, Mesoamerica in its inception referred to the arrangement of indigenous cultures and language groups of this area at the time of contact with Europeans in the sixteenth century. More generally today, the term is used for cultural developments comprising the long swath of time between early human migrations and settlement starting some 10,000 years ago and right up to contemporary embodiments of traditional cultural continuities, be they Postcolonial struggles with identity definition, immigration issues, or indigenous rights movements. As a simplified chronology, Mesoamerica can be divided into an Archaic period, running up to roughly 2000 BCE, a Preclassic period ending about 250 CE, a Classic period up until 900 CE, a Postclassic period ending with the fall of Aztec Tenochtitlan in 1521, and a Colonial and Postcolonial period between 1521 and the varying dates of national independence, with the Mexican Postcolonial period starting in 1821.

Within its physical setting, the concept of Mesoamerica includes several indigenous societies and the worldviews inspired by the relationship between people and their environments. Many diverse ecosystems are part of Mesoamerica's backdrop and can be grouped under three altitude-defined areas: *tierra fría* (high-altitude plateaus with volcanoes), *tierra caliente* (tropical rainforest lowlands), and *tierra templada* (the elevations in-between, with dry forest valleys). The diversity in ecosystems produced materials prized and traded throughout, between highlands and lowlands environments since early on, among which are jade, basalt, obsidian, salt, and perishable prestige items like feathers. Animals, especially those from the lowland tropics like jaguars, deer, monkeys, caimans, and several types of birds, including the turkey, also held symbolic importance in addition to providing sources of food and material for craftwork. Among the food items prevalent throughout Mesoamerica, the triad of early American domesticates – maize, beans, and squash – is a cornerstone of the intersecting cultural identities of Mesoamerican peoples, who might otherwise belong to different ethnicities and language groups. Among all foods, maize represents the most important staple, with consequent symbolic relevance in many cultures, such as the Maize

God of the Maya, but cacao also played an important role in long-distance trade out of the lowlands and, in addition to exemplifying a prestige product, may have functioned much like a form of currency.

For Mesoamerican people, environments themselves hold symbolic importance, especially those in connection with water and mountains. In particular, unique environments like the karstic limestone shelf of the Yucatan peninsula, which is studded with sinkholes, caverns, and underground streams, lend a supernatural quality to water scarcity. Caves and points of access to deeply buried water sources symbolize portals to the underworld and access to the realm of gods and godly resources. Caves are symbolically important throughout Mesoamerica and come to embody places of entry into and exit from other worlds – often the place of emergence of mythical human ancestors. Mountains (and volcanoes) are also locations of emergence: mythical Eden-like places enclosing precious life forces and goods. Ancient pyramid building practices create associations between artificial and natural mountains, constructing the appropriate places for the worship of gods, the burials of the elite, and the caching of offerings and sacrifices to deities.

Symbolism linked to concepts of space and directionality is of particular importance in many Mesoamerican societies and varies with each, but fundamental similarity in world view links spatial patterns from households to entire settlements and from commoner contexts to royal ones, with symbolic associations to an idealized cosmogram. The basic conception of the world is one of space divided into four quarters or directions in the form of a cross, with a center point acting as the most sacred direction, creating a quincunx patterning of space. This quadripartite scheme is reflected also in architectural layouts, as in the plan of radial pyramids, with a staircase on each of the four sides ascending to a central point at the top. Each direction in the cosmogram has cognate symbols, for example associated colors (among the Maya, red for east and the rising sun, white for north, black for west, yellow for south, and green – the color of precious jade – for the center). The directional symbolism of quadripartite structures also links space with time, as it traces the path of the sun from its rise in the east, passage through the zenith, setting in the west, and return through the underworld to its eastern point of emergence. With the cosmos divided into the upper layer of the heavens, the earthly surface, and the underworld below, the path of the sun also provides the mechanism connecting the layers of the cosmos and creates a parallel between quadripartite patterns and the notion of completion of cycles. The passage of time in ancient Mesoamerica was reckoned as cyclical (in particular, a 365-day solar cycle and a 260-day divinatory one), and this conception of time established links between cosmological, astrological, and agricultural cycles.

Despite these general definitions of Mesoamerica as a cultural concept in which shared beliefs between different traditions go back millennia and are evident in daily customs, Mesoamericans are not a single culture and have not traditionally viewed themselves as participating in a common identity. The term Mesoamerica dates to the 1940s and was devised as an analytical term, to allow for the classification of a group of cultures on the basis of shared traits.

Historical Background

Mesoamerica is a widely used term, but as an analytical concept, it is far from representing academic unity in the perception of its validity and continues to be a source of animated debate, especially in Mexico, where it developed and where it has been extensively adopted since its proposal in the 1940s. The classification of several societies straddling North and Central America into the cultural concept of Mesoamerica began with the 27th International Congress of Americanists held in Lima, Peru, in 1939, among members of the Comité Internacional para el Estudio de Distribuciones Culturales en América. It was followed by a formal definition of the term by German social anthropologist Paul Kirchhoff, who was working in Mexico and who published his proposal in Spanish in *Acta Americana* in 1943 and subsequently in an English translation

in 1952. The term was initially accepted and adopted without much controversy, mainly by archaeologists, ethnohistorians, and linguists, and less so by physical anthropologists, ethnologists, and sociocultural anthropologists, who to this day and especially in North America tend to make less use of this classification (scholars who call themselves Mesoamericanists tend to be archaeologists, not cultural anthropologists). Debate followed after decades, upon analysis of how the application of the term had morphed over time. Among the chief critical commentaries was that of Kirchhoff himself in the 1975 preface to the third edition of the original publication, in which he expressed disappointment in how his initial call for a productive use of the term had not been heeded with critical evaluation, and the concept was being adopted without serious consideration for its potential.

In the seminal 1943 paper in *Acta Americana*, Kirchhoff created the concept of Mesoamerica by grouping cultures on the basis of a series of shared cultural traits and practices, thereby establishing patterns of belonging and exclusion based on the presence or absence of those traits. The resulting groupings formed Mesoamerica as a cultural area, reflecting the anthropological scholarship of the time in its culture historical and classificatory tendencies, of which Kirchhoff's lifetime work is an evident example. While today the list of traits is the most commonly remembered aspect of Kirchhoff's method for the definition of Mesoamerica, his intentions stemmed from the recognition of a problem in defining the boundaries of culture areas. Kirchhoff objected to a geographic classification of indigenous groups into either North or South American, following biogeographical boundaries, and to the alternative division into Middle America, separating cultures from North and South American ones. He argued that geographical boundaries do not constitute cultural boundaries and that in some cases indigenous cultures of Mexico had less in common with neighboring ones to the north, with which they were grouped into the unit of North America, than they had with ones in South America, from which they were separated geographically and by extension culturally. In creating the term Mesoamerica, Kirchhoff meant it as an analytical term, or a theoretical construct, allowing for distinction from political and geographical boundaries, which remained purely descriptive. In this way, Mesoamerica did not exist as a reality reflected in tangible elements, but as an interpretive and analytical "problem" to address with investigations focused on explaining the presence or absence of elements and their historical trajectory. Despite Kirchhoff's intentions that Mesoamerica be more than just a framework for defining an area of investigation, that nevertheless became its most common usage and led to the development of critical objections to its validity in the first place.

Today, the temporal frame of reference of Mesoamerica is best envisioned in long and flexible spans of time because establishing chronological boundaries is equally as complex as defining cultural ones in geographical terms. In establishing his classification of cultures in the 1940s, Kirchhoff looked to the distribution of language groups "at the time of the conquest" (Kirchhoff 1952: 19), placing his original definition of Mesoamerica into a sixteenth-century context. Subsequently, as the term was adopted more by archaeologists than other anthropologists and historians, it most frequently came to refer to indigenous pre-Hispanic civilizations from much earlier times. Lately, new awareness recognizes that this traditional usage creates "terminological problems" in addressing the "mestizo, European, and even indigenous peoples who had little or nothing to do with the so-called Mesoamerican world but have resided in the region for centuries" (Carmack et al. 2007: 5–6). Contemporary definitions now acknowledge that Mesoamerica includes "not only the rich historical, social, and symbolic traditions of diverse aboriginal cultures (before and after European contact) but also the interweaving of these with European and African traditions from the Spanish conquest to the present" (Carrasco 2001: 212).

In tracing distributions of language groups, Kirchhoff classified Mesoamerican peoples into contact-period linguistic entities that approximated ethnic groups with shared histories and therefore brought out cultural boundaries. He

used language and history as forms of identity definition based on community and reinforced by differences with people beyond the group. In Kirchhoff's words, "this all demonstrates the condition of Mesoamerica as a region whose inhabitants, both the very early immigrants and those relatively recent, were bound by a common history that placed them as a group in front of other tribes of the continent, leaving their migratory movements confined, as a general rule, inside its geographical limits once they were within Mesoamerica's influence" (Kirchhoff 1952: 20). Aspects of a common history resulted in elements shared between or lacking from individual societies and allowed Kirchhoff to compile a list of over 40 elements exemplifying "Mesoamericanness." These shared traits can be grouped into categories that include elements of farming (like corn and cacao), personal adornment and clothing, architectural features (pyramids), writing and computation (such as hieroglyphs and positional numerals), calendar systems (ritual and solar years which combined form a 52-year "century"), components of ritual practices and sacrifice, and military aspects. Many of these categories had direct usefulness for archaeologists, regardless of whether the trait list was an efficient method of analysis. The broader strength of this proposition was the argument for a greater commonality, between cultures previously treated as discrete entities, of lifeways and worldview, of which stepped pyramids and ball courts are material manifestations and therefore subject of study for archaeology.

Among the first scholars who found the term useful and began applying it in their work is the Mexican scholar Pedro Armillas, who adopted aspects of Kirchhoff's Mesoamerica in a discussion of its cultural frontiers along rivers (1951). Armillas had developed a critical attitude toward Mexican archaeology during the early 1940s, targeting the shortcomings of traditional archaeological research design of the time, which focused on studying ceramic sequences in order to establish cultural chronologies. In the United States, Clyde Kluckhohn had published similar critical attacks on Mexican and Central American anthropology (1940), setting the stage for a reorganization of Middle American studies to include more theoretical goals, broader frameworks of analysis, and more generalizing formulations geared toward uncovering cultural universals. These new theoretical influences from Marxist ideologies also imparted tendencies toward cultural evolutionism to the establishment of Kirchhoff's concept of Mesoamerica.

Unfortunately, because Kirchhoff approached anthropology as a historical discipline, the application of Marxist and evolutionist notions of the time also meant that the reorganization of cultures around his trait list resulted in a developmental sequence in which Mesoamerican civilizations emerged as the "super area of higher farmers" (Kirchhoff 1952: 19). This attribution of low-to-high cultural levels to people along evolutionary lines is still one of the enduring weaknesses of the concept of Mesoamerica. Through it, Kirchhoff assigned to many of what he called "tribes" in the northern and southern reaches of Mesoamerica a low level of "culture" and designated the core areas of Mexico as the height of civilization. Further (as discussed below), evolutionary sequences led to the perception of a single developmental sequence, that in turn created the erroneous impression of a single uniform Mesoamerica in which cultures could be seen as derivative of one another – a practice that resulted in a largely diffusionist paradigm of Mesoamerican cultures.

Beyond the 1952 translation of Kirchhoff's definition of Mesoamerica, the term was used interchangeably with Middle America (the term then common among North American archaeologists) in Willey and Phillips's 1958 *Method and Theory in American Archaeology*, from which it became widespread beyond Mexico. The decades that followed saw developments in archaeology that were appropriate for a field of Mesoamerican studies, considerably more multidisciplinary and interregional than any in the preceding half century. Among the archaeological work that rested on the concept of Mesoamerica are regional projects, surveys, and settlement pattern studies; research in cultural ecology and human adaptations to the natural environment; long-distance trade and interaction; and the investigation of social evolution and culture change, urbanism,

and the development of civilizations and the state. Starting in the 1940s, systematic research began to expand into regions beyond the traditional focus on the Basin of Mexico, Oaxaca, and the Maya area, and all the way to the frontiers of Mesoamerica. The formulation of a concept for a Mesoamerica distinct from geographical and political classifications also resulted in evaluation of methodological approaches, in several synthetic works on archaeological aspects of the area and in archaeological publications placing culture areas within their larger Mesoamerican context, among which Marquina's (1951) *Arquitectura Prehispánica*, Piña Chan's (1960) *Mesoamérica*, Norguera's (1965) *La Cerámica Arqueológica de Mesoamerica*, Sanders and Price's (1968) *Mesoamerica: The Evolution of a Civilization*, and Flannery's (1976) *The Early Mesoamerican Village*.

Key Issues and Current Debates

One of the advantages of the term Mesoamerica, as well as what sparks much of the disagreement around the concept, is that it is full of ambiguity, deriving from the nature of the elements considered for its initial definition. Today's anthropological approaches cannot reduce culture to a formula for presence or absence of traits, but the method was typical of the classificatory period of culture history. Ambiguity also stemmed from the fact that the original concept was somewhat devoid of a discussion of its temporal dimensions, and the geographical distribution of the characteristic elements was not homogenous through space within each society. These compounded sources of ambiguity result in a cultural concept for Mesoamerica that identifies different ethnic groups, but the sum of these parts does not equal a single culture. Consequently, the developmental trajectory of Mesoamerica as a cultural tradition has multiple historical strands, at times interwoven in temporally and geographically heterogeneous ways.

Within the classification of New World societies into culture areas, the development of the notion of Mesoamerica is a contribution from Mexico to worldwide archaeology, and therefore, such a fundamental part of the discipline in that nation that for a long time analysis of its strengths and weaknesses has been beyond the realm of questioning. Recently, however, Mexican scholars in archaeology and related disciplines have attempted to systematize and coordinate the various voices of the debate on the continued appropriateness of the concept of Mesoamerica that have periodically questioned its validity since the death of Kirchhoff and even earlier. One such effort resulted in a symposium followed by a special issue edited by Ignacio Rodríguez García (2000) in the journal *Dimensión Antropológica* of the Mexican Instituto Nacional de Antropología e Historia. The aim of the journal is to address issues of national and international relevance to the theoretical and conceptual framework of anthropological research. Because of the deep tradition of Marxist approaches in Latin American anthropology, the issue dedicated to debating the concept of Mesoamerica is also a philosophical debate on the nature of knowledge, determinism, and the lack of theories of change in positivist science. What is clear to scholars in Mexico, more than to others who use the term Mesoamerica, is that it only has the appearance of a descriptive designation defining the extent of an area but that probing its theoretical implications is both an anthropological discussion and a debate on the intentions and legacy of Kirchhoff's contribution to Mexican and global anthropology. As López Aguilar asserts, "Mesoamérica se corrobora e intentifica con la tortilla, las navajas prismáticas, el juego de pelota, Tláloc, las sociedadedes complejas o *clasistas iniciales*, la mexicanidad, el nacionalismo, el México profundo o con cualquiera de los rasgos culturales *ad hoc* que propuso Kirchhoff y que se siguen manejando por los arqueólogos, con una carga teórica que no se ha reconocido hasta ahora" (2000: 107) (Translation by author: "Mesoamerica is corroborated by and identified with the tortilla, prismatic blades, the ballgame, [the rain god] Tláloc, complex societies or pristine states, mexicanism, nationalism, and deep Mexico or whichever of the ad hoc cultural traits proposed by Kirchhoff and that continue to be employed by archaeologists, with a theoretical load that has not

been recognized until now."). The critique warns that once accepted as a term reflecting a reality, all research results serve to reaffirm and reify Mesoamerica as a discrete entity: evidence is never used to confront the notion, explain its validity, argue against its usefulness, or question its very existence as a cultural certainty.

In broader terms, the use of the concept of Mesoamerica over nearly 70 years has developed its own historical trajectory in which its meaning has been ascribed changing values by different scholars and at different times. Some aspects of its history constitute weaknesses that are apparent in hindsight. For example, as Kirchhoff's and colleagues' ideas originated in an environment of Mexican nationalism that reinforced the concept of monumentalism, high culture, and the ideology of the state, the idea of Mesoamerica can be read as a teleological argument for the culmination of certain lifeways into a civilizing process defined by "higher farmers" to distinguish them from lesser farmers and hunter-gatherers. This approach neatly identified the core of Mesoamerica with the core of the Mexican nation, heir to the achievements of the civilizations of the Aztec, Toltec, and Teotihuacanos, and as such appealed to the government and to a state-supported vision of the Mexican past. The Mesoamerica that was intended to bridge fragmented research efforts into a cohesive whole and to represent all its societies as an interwoven cultural unit often resulted in the alienation of many groups whose cultural trajectories did not fall into the grand historical heritage envisioned by a national narrative.

The effects have often been practical, as in the favoring of a few cultural traditions over the whole, which resulted in direct intervention and government support to finance research projects and monumental site restoration for those endeavors that promoted the earliest origins and highest achievements of the grand civilizations of Mesoamerica. The perception of a grand sweep of historical evolution derives from Kirchhoff's original classification, though the effect may not have been in his intentions. One of the weaknesses of a typology of traits is that, once mapped onto a geographical distribution, it leads to a tendency, of which Kirchhoff himself was not free from, to explain the origin and spread of things through diffusion.

One such example is the role of the Olmec in the origins of civilization in Mesoamerica, a debate that has been ongoing since Frans Blom's and Oliver La Farge's 1920s survey of the Gulf Coast but that saw increased intensity after Kirchhoff's proposal of a Mesoamerican cultural unit and became an argument in favor of the Olmec as a "mother culture" with the 1942 Round Table of the newly founded Sociedad Mexicana de Antropología. The concept of Mesoamerica allowed for the impression of a single linear developmental trajectory, engendering a disposition to see one culture as derivative of another and ultimately all Mesoamerican cultures as derivative of a single one. With the dating of Olmec remains showing great antiquity, the Olmec became the case for the original civilization of ancient Mesoamerica, and the *cultura madre* debate continues unresolved today. In generalized terms, among the supporters of an Olmec origin of civilization, Diehl and Coe (1996) place the scholars and national institutes directors of great influence in Mexican archaeology, like Alfonso Caso, Miguel Covarrubias, and Ignacio Bernal, while researchers of other societies, like the Zapotec and the Maya, belong with the proponents of an alternative view in which Mesoamerican civilization is the combined result of many equal donor cultures. The debate is often driven by findings of newer and earlier examples of "traits" that occur first in any one society and therefore remains somewhat local, missing the opportunity for an analysis of the entire paradigm of "mother cultures" and whether this constitutes an appropriate model for the development of complex societies, in Mesoamerica or elsewhere.

Despite the above example of a less than fruitful consequence of the classification of cultural groups into a single Mesoamerica, the concept also has great power as an analytical tool for comparative approaches to Mesoamerican cultures, both within Mesoamerica and beyond it. A demonstrated strength of the concept of Mesoamerica is the example of its use in the analysis of Teotihuacan's interaction sphere, by scholars of

Teotihuacan as well as of several other Mesoamerican peoples. In addition to analysis of the legacy inherited by the Aztec and other Postclassic societies, in the study of Teotihuacan's spread of ideas and people into the Maya area in the early Classic period, a common broader view has allowed for very useful integration of separate culture histories into a much more complex pattern of reciprocal influences (see Carrasco et al. 2000; Braswell 2003). Much is still unclear about the nature of the interactions with the Maya, but a Mesoamerican lens is the appropriate approach to understanding Maya sites with particular traits not common to all sites and to understanding Maya and other ethnic barrios in Teotihuacan's urban core.

Beyond comparative approaches within Mesoamerica, the idea first proposed by Kirchhoff embodies the potential for strong multidisciplinary and cross-cultural discussions in a global context, which despite other weaknesses expressed here, imparts a validity and usefulness to the concept, whose possible theoretical contribution has yet to be fully explored from an international perspective.

International Perspectives and Future Directions

The inherent ambiguity in the concept of Mesoamerica has consequences for the role of the term in a global context. Whether debates center on ontological or theoretical discussions, Mesoamerica remains insufficiently solidly defined to be easily incorporated in worldwide visions. In simplistic terms, among scholars working in Mesoamerica, two camps can be identified: those who use the term widely but do not pose themselves the problem of querying its validity and those who are aware of its history and etymology but squabble over its contemporary limitations. Of the latter, scholars take issue with several of the shortcoming among which those discussed here and argue that its limitations are greater than its advantages, while others who support its validity often do so on the grounds of respect for Kirchhoff's historical contribution. Generally missing is a camp of supporters of the concept of Mesoamerica based on the renewed contemporary advantages it offers in a global context of cross-cultural archaeological inquiry.

While scholars who support the idea of Mesoamerica have seen uniformity, others in the world have sensed the heterogeneity of the concept of a Mesoamerican civilization defined differently for each time and place, making for ad hoc comparisons with the other early civilizations of the world: Egypt, Mesopotamia, the Indus Valley, China, southwestern Nigeria, and Peru. For example, if referring to a "Neolithic Revolution," we should look to the Tehuacan Valley of five millennia ago; if to the origins of complexity, then to the Maya, the Olmec, and the Zapotec of the early mid-first-millennium BCE; if to elaborate writing systems, to the Mixe-Zoque and the Maya before the first millennium CE; and if to urban societies, then to Teotihuacan in the first millennium BCE. However, as the deep history of long-distance trade in obsidian attests, these cultures did not exist over 4,000 years in isolation from each other and instead shared contact and exchanges of goods and information. Nevertheless, the above confusion as to exactly which society we refer to when speaking of a Mesoamerican civilization suggests that the concept of Mesoamerica could use fresh redefinition, perhaps acknowledging its historical roots but specifically formulated to be useful to a worldwide discussion of archaeological civilizations, so that Mesoamerican societies can be considered in a global context. An integrated approach to the study of complex societies that systematically includes Mesoamerican ones would advance a global history of comparable trajectories with the richness of local details.

Another great strength of the original classification lies in the fact that the concept is not defined by a chronological framework. While originally bound by contact period data, the term is inherently temporally flexible and today has come to encompass also Colonial and Postcolonial modern periods. In this realm, scholarship has demonstrated dynamic interaction of ideas between Europe and Mesoamerica that include Spanish, indigenous American, and African traditions (ethnographies and historical records, maps, ideas on religion, humanity, and

nature). As Carrasco, who supports the idea of a Mesoamerica not limited to pre-Hispanic times, reminds us, "the encounters and exchanges among various European cultural groups, diverse indigenous cultures, and African peoples did not represent a termination of indigenous cultural practices, but rather the formation and transculturation of new worlds for Europeans, native peoples, and *mestizos*, mulattos, and *castas*" (Carrasco 2001: 213). Today's scholars recognize that interactions in Mesoamerica in post-contact times have spurred developments in natural history, theology, and philosophy in Europe (during the Enlightenment), which subsequently informed models of biological, social, and political change (now described in such terms as evolution, syncretism, and revolution). These views, rather than treating Mesoamerica as part of a New World in opposition to an "old" one, argue for a New World that is the unprecedented outcome of two old worlds coming together – a perspective that is more consonant with global archaeological inquiry.

Kirchhoff's original proposal assumed that Mesoamerica was an identity concept shared by those people he had grouped under the term, when in reality it is a classificatory notion imposed from a typological perspective. Its value is analytical and cannot be confused with a retrofitted sense of identity for indigenous Mesoamerican groups. But, whether or not we can consider a common identity to be perceived as such, we may be able to observe it empirically in material traces, and such a practice has made the term Mesoamerica useful to archaeologists. Perhaps not in terms of the specific ethnic and linguistic groups, evolutionary stages, or shared traits, nevertheless Mesoamerica exists: as an area of shared cultural characteristics expressed in practices and ideological values resulting from diverse developmental trajectories in a context not devoid of contact and exchange.

Mesoamerica: Subsistence Strategies by Region

Guillermo Acosta-Ochoa
Area de Prehistoria y Evolución, Instituto de Investigaciones Antropológicas, Universidad Nacional Autónoma de México, Circuito Exterior s/n Ciudad Universitaria, Del. Coyoacán, DF, Mexico, DF, Mexico

Introduction

Establishing subsistence strategies for Mesoamerica appears quite simple; it would suffice to separate periods associated with hunter-gatherers from those in which agrarian societies appear. However, in practice, the situation is more complex. In addition to the fact that domestication represents a long process that cannot easily be considered to be completed, almost all societies at the time of the arrival of the Spanish continued to use hunting, fishing, and gathering as important parts of their obtaining nutrition.

Additionally, periods before the emergence of so-called complex societies have been little studied in comparison with ceramic periods. For this reason, available information regarding earlier subsistence strategies, such as those of the hunters of megafauna, gatherers from the coasts or the interior, and early agriculturalists, is scarce and fragmentary.

Finally, the differentiation carried out in this text regarding subsistence strategies is somewhat idealized in that it distinguishes three large groups: a. hunters of megafauna, b. coastal and broad-spectrum gatherers, and c. agrarian societies. This distinction is made simply to define the essential aspect that dominates each these subsistence strategies, without excluding other, secondary activities in obtaining food.

Definition

Subsistence

Subsistence implies all the strategies and material means that an individual or human group employs

for their survival and reproduction, whether biological or cultural. Thus, it is not synonymous with forms or levels of social integration, such as the terms "band," "tribe," "hierarchical societies," and "archaic state." Nevertheless, each form of social organization can be linked to specific subsistence strategies: For example, societies defined as "bands" (Service 1962) are characterized by a mode of subsistence based on hunting, fishing, and gathering, whereas in hierarchical or state societies, subsistence is generally based on agriculture.

Hunter-Gatherers

Hunter-gatherers are human groups whose subsistence is based on the hunting of wild animals and the collection of wild plants without their domestication and, with the exception of dogs, without domestic animals (Lee and Daly 1999: 3).

Big-Game Hunters

Extinct animals whose weight usually was over a half-ton are considered megafauna, although this term is generally employed to designate megaherbivores, such as the mammoth (*Mammuthus*), mastodon (*Mammut*), or giant sloth *Megatherium*, *Eremotherium*). Although the Paleo-Indian cultures of the end of the Pleistocene have generally been defined as hunters of megafauna, it is likely that Clovis hunters and other contemporary groups were only occasional hunters of this type.

Broad-Spectrum Foragers (Coastal and Continental)

These groups are oriented toward the collection of plants, mollusks, and smaller fauna and are usually associated with coastal and tropical zones of Mesoamerica, although they are not exclusively from these regions. Even if these groups are identifiable since the end of the Pleistocene, this way of life became widespread in the Mesoamerican zone, beginning with the Holocene.

Cultivation

This is the artificial human propagation of seeds, cuttings or roots, and/or care of plants, whether wild or domesticated.

Agriculture

In this cultural system, subsistence is based on domesticated plants. Agricultural production can be separated into two systems of agriculture: intensive and extensive. Extensive agriculture requires a relatively large area of land and is defined as following the cultivation of a parcel of land by a fallow period (which depends on the characteristics of the soil, but may be of up to seven years), during which the soil is allowed to reconstitute its nutrients.

Sedentarism

This process involves the permanent establishment of human settlement in contrast with nomadism, which involves the constant moving of camps to different territories due to causes such as herding, a reduction of the capacity of the environment, or the need for allochthonous resources. Although in the greater number of archaeological and ethnographic cases, sedentarism tends to be associated with agrarian societies, this association is not universal. In particular, sedentarism is a notably late process in Mesoamerica in comparison with the appearance of the first domesticated plants in this region.

Historical Background

The study of subsistence in Mesoamerica has been linked with the development of archaeology itself in Mexico and Central America. Most likely, the oldest discussions in this regard began with the debate at the end of the nineteenth century between Florentino Ameghino and Aleš Hrdlička. The former argued that modern humans had evolved in South America and subsequently migrated to the rest of the planet; in contrast, Hrdlička denied the idea that humans had originated in the Argentine pampas but also denied that they could have coexisted with the fauna of the Pleistocene. Later, the findings at Folsom, New Mexico, in 1908, would confirm not only coexistence between humans and Pleistocene fauna but also the possible hunting of such fauna.

During the first half of the twentieth century, many studies of Mesoamerican societies focused

on defining cultural sequences and the chronological position of the various regional cultures; therefore, the study of ceramics, sculpture, and architecture was central to defining regional styles. Although complex societies were the principal subject of this research, studies on subsistence systems prior to the development of ceramics were marginal. This condition held true until the discovery of the so-called Tepexpan Man in 1947, when the investigation of preceramic societies began in earnest, particularly in Mexico; various research projects on hunter-gatherer groups were carried out after the creation of the "Department of Prehistory of the INAH [the National Institute of Anthropology and History]." At this time, research also began on coastal gatherers, and research until the mid-twentieth century had a marked focus on cultural history.

In the second half of the twentieth century, ecological perspectives began to dominate archaeological investigations that were centered on defining agricultural systems, their productive potential, and their role in the development of complex societies (Sanders et al. 1979). Additionally, the first long-term studies examining the development of agriculture began, principally in the Tehuacán and Oaxaca valleys (MacNeish 1967; Flannery 1986). The last 3 decades have seen a marked change from research with an ecological and evolutionary focus to studies involving nonlinear dynamic models, as well as models where individuals are considered to be active agents in the models of change. Conversely, the application of new techniques for the recovery of evidence (both direct and indirect) for human subsistence (i.e., phytoliths, starch grains, pollen, chemical analyses, and stable isotopes, among others) has permitted the evaluation of traditional models of the origin of agriculture or the paleodiet and the generation of new research trends.

Key Issues/Current Debates

Early Peopling and Big-Game Hunting

Although it is clear now that the peopling of the American continent took place at the end of the Pleistocene through the Bering Strait, various opinions remain regarding whether this migration took place through the interior of the continent or along the coast, as well as the time at which this process occurred.

One group of researchers argues that this initial peopling must have taken place at the end of the last glaciation (Wisconsin) and suggests that it was not possible until the two large glacial blocs that covered North America (the Laurentide and Cordilleran) had melted between 11,000 and 12,000 BCE. This model (termed *Clovis-first*) suggests that the first settlers were hunters who used fluted points (Clovis) and entered through a hypothetical "ice-free corridor," a thin fringe of exposed land that existed between both glaciers and allowed passage through the area now occupied by Alberta (Fiedel 1996: 72).

The *Clovis-first* model assumes an accelerated "migratory wave" of groups hunting Pleistocene fauna that would go on to carry out a rapid peopling toward the south of the continent and would be responsible for the extinction of the megafauna. Unfortunately, this model presents several problems. Paleoecological studies have shown that this supposed corridor was either impossible or did not exist until very late in the Pleistocene, when the continent was already populated. The model also does not consider the large differences in the gradient of ecosystems located between North and South America, nor does it explain the presence of fully accepted pre-Clovis sites in the New World, such as Monte Verde in Chile.

In Mesoamerica, a large quantity of fluted points have been found, almost all of which are from the surface, from the Sierra Gorda de Querétaro to Honduras (Acosta 2012). These fluted points, which are found from southern Mexico and Central America, are not "typical" Clovis points but are characterized by reduced dimensions and concave edges such that they are more similar to the points of the late Paleo-Indian period of the USA. These points can be associated with points of the "fishtail" type, as in Chiapas or Belize, although the associated stone tools correspond to those typically associated with Clovis, such as "keeled" scrapers (*limaces*), burins, and

scrapers with lateral spurs; these tools indicate a type of subsistence that is highly dependent on hunting and uses specialized artifacts for removing flesh from prey and preparing skins. Only for Los Grifos, Chiapas, has a study reported on the remains of fauna from Clovis settlements, indicating medium-sized prey, such as white-tailed deer (*Odocoileus* sp.), peccary (*Tayassu* sp.), and Pleistocene horse (*Equus* sp.).

Only two Clovis sites in the Mesoamerican area have been dated: Los Grifos in Chiapas, Mexico and Los Tapiales in Guatemala. Unfortunately, the early dates for Los Tapiales (c. 10,500 BCE), Guatemala, do not appear to be clearly associated with the Clovis materials, and the site presents various dates from the early Holocene. The dates for Los Grifos (9,000–8,000 BCE) time the appearance of fluted points in Mesoamerica mainly at the beginning of the Holocene (Acosta 2012).

The association of megafauna with human activity has best been documented at the Valley of Mexico, although many of these sites do not contain diagnostic materials that could associate them with any particular Pleistocene technology. The megafauna (*Mammuthus columbi*) hunting sites associated with projectile points include those for mammoths at Santa Isabel Iztapan and three points associated with them (Lerma, Plainview, and Angostura) in combination with other artifacts linked to the processing of prey. Other sites, such as Atepehuacan, contain mammoth remains that are associated with obsidian flakes. These two sites are dated at the beginning of the Holocene, between 9,500 and 9,000 BCE (Aveleyra 1967).

Despite these datings, sites for megafauna hunting in the Valley of Mexico to date correspond to killing sites; however, base camps have not been located that would allow us to determine whether these great preys were important in the subsistence of these early settlers or these remains only reflect occasional hunting (and most likely scavenging) of the last megamammals that were in the process of extinction at the end of the last ice age.

Coastal Collectors and Broad-Spectrum Hunters

Human groups have exploited coastal resources since the end of the Pleistocene. Indeed, several authors believe that the peopling of the continent must have taken place along the Pacific coastline earlier than the peopling of the continental interior (Dixon 1999). The earliest evidence of coastal collecting groups appears along the entire Pacific coast from the California islands to Chile. These groups show a marked dependence on collecting marine mollusks; however, depending on the region, the hunting of birds, fish, and marine and terrestrial mammals can also be observed.

In the Mesoamerican region, the earliest evidence of coastal occupation comes from submerged caves in the Yucatan Peninsula, where human remains have been recovered that date between 7,000 and 10,000 BCE, although no other cultural materials were present (González et al. 2008). Most of the coastal sites of Mesoamerica correspond to the period known as Archaic (10,000–4,000 BCE) because sea levels stabilized after 7,000 BCE. Although there is a void in the research on the Pacific coast for periods prior to 7,000 BCE, coastal sites have been located (principally "shell middens") along the entire Pacific coast; in Sinaloa (El Calón, 1,800 BCE), Nayarit (Matanchén, 2,500–2,000 BCE), Guerrero (Puerto Marqués, 2,200 BCE), and Chiapas (Chantuto, 5,000–2,500 BCE) (Kenneth 2012).

In the continental interior, groups of broad-spectrum hunter-gatherers based on subsistence linked to the hunting of smaller fauna and the collection of wild plants can be observed from the Pleistocene-Holocene transition point, approximately 10,000–9,000 BCE. In zones such as the Sierra de Tamaulipas (Ocampo), Puebla (Tehuacán Valley), the Valley of Oaxaca (Guilá Naquitz), the Central Depression of Chiapas (Santa Marta cave), and the Honduras Plateau (El Gigante Cave), these groups show mixed subsistence based on the hunting of deer, rabbits, and peccary, the capture of animals such as turtles, and the collection of freshwater snails (Santa Marta).

Collection includes fruits from cacti in arid zones, pine nuts and acorns in forested regions, as well as fruits from tropical trees in more humid zones. One point worth emphasizing is the use of millstones since the Late Pleistocene in sites such as Guilá Naquitz, Oaxaca, and Santa Marta Rockshelter in Chiapas, which indicates a growing increase in the dependence on plants and their processing. Archaeobotanical remains indicate that these broad-spectrum subsistence groups are responsible for some of the earliest domestications in the Mesoamerican zone (Piperno and Smith 2012).

Domestication and Early Agriculture

Recent data indicate that the first domestications took place in groups that maintained a hunter-gatherer pattern of subsistence. It is probable that at least two species (the domestic dog and *Lagenaria* or bottle gourd) entered the continent, having already been domesticated, together with the first settlers at the end of the Pleistocene. The oldest domesticated plant found from the early Archaic Period (c. 10,000–8,000 BCE) is the pumpkin, located at the lower levels of Guilá Náquitz in the Valley of Oaxaca. These first domesticated plants do not appear to be related only to nutritional purposes but also to other aspects of subsistence, such as the transport of water (squash and the bottle gourd) or use as stimulant plants (*Theobroma*) and the production of fermented beverages (*Zea Mays*). In the Balsas river Basin, the region which is considered to have given rise to the ancestor of maize (*Zea parviglumys*), the remains of phytoliths of *Cucurbita argyosperma* (silver-seeded squash) have been located, and grains of corn starch, dated to 6,700 BCE, have been associated with stone mortars (Ranere et al. 2009). The earliest dates carried out directly from the remains of maize come from Guilá Naquitz and are dated to 4,200 BCE.

In the Paleoecological records of the tropical lowlands of Mesoamerica, a sudden increase in the appearance of maize pollen associated with a reduction in the amount of forest and an increase in weeds can be observed between 5,500 and 5,000 BCE. This finding has been interpreted as a change in agricultural techniques from an incipient agriculture or horticulture to a slash-and-burn agriculture, as can be observed in the Balsas river Basin (Ranere et al. 2009), the Pacific Coast (Kennett et al. 2010), and the Olmec zone of the Gulf of Mexico (Pope et al. 2001). In these regions, an accelerated change toward the transformation of tropical forest (including mangrove swamp) into agroecosystems can be observed, including plants originating from South America, such as manioc (*Manihot* sp.), at approximately 4,500 BCE. It is likely that this period corresponds with a true agricultural revolution in Mesoamerica, as demonstrated by the systematic modification of the environment into an agrarian landscape and the establishment of the system of milpa and its implications for the economic and religious structure of the communities. This agricultural revolution, beginning in the tropical lowlands, appears to have been adopted later in other regions, such as the Valley of Mexico and the Mayan Zone, where similar conditions can be observed after 4,000 BCE.

Sedentary Life and Agricultural Societies

The residence pattern of early hunter-gatherers (10,000–8,000 BP), including those of the early Archaic that exhibit evidence of domesticated plants, was one of high mobility and low demographic density. Cristine Niederberger (1979) has suggested two models for the mobility for incipient agricultural societies as follows: a) the "Tehuacán Model," applicable to the semiarid regions of Puebla, Tamaulipas, and Oaxaca, that exhibit a marked period of productivity associated with the rainy season; this model involved the aggregation of large communities (macrobands) dedicated to the extensive exploitation of cereals and other plants during the season of greatest fertility. In contrast, during the dry season, these groups would disperse into smaller groups (microbands) with the tasks of hunting and collecting in various ecological niches. Although

these groups show that certain early agricultural practices had developed by at least the sixth millennium BCE with plants such as maize, chile, avocado, and squash, a sedentary way of life was not observed for these groups until at least three millennia later. b) The model developed for Zohapilco and most likely other regions of higher annual productivity (such as the Pacific coast and other sites from the Mesoamerican lowlands) suggests that the societies of the sixth millennium BCE show territorial and sedentary occupation associated with the lacustrine environment (most likely linked to a period of climatic optimum and associated with a highly productive lake environment, where resources could be obtained during almost the entire year), exhibiting evidence of incipient agricultural experimentation with plants such as *Zea* (tesosinte), *Amaranthus*, and *Physalis* (tomato) for the period between 6,000 and 4,500 BCE. During the Zohapilco phase (3,500–2,200 BCE), however, a notable increase in the appearance of domesticated plants and stone artifacts associated with their processing (metates and manos) can be observed; thus, the model established by Niederberger indicates a marked period of sedentarism within a pre- and protoagricultural context. This model, however, is atypical for the rest of Mesoamerica because a fully established sedentary pattern does not appear to have been established until the period when ceramics appeared between 2,000 and 1,500 BCE.

Between 1,600 and 1,000 BCE throughout practically all of Mesoamerica, permanent communities developed based on extensive seasonal agriculture that was associated with fertile lands in lake zones, such as the Valley of Mexico and the Guatemala Petén, or on river banks in Oaxaca and the coast of the Gulf of México; these communities also developed in coastal zones rich in marine and terrestrial resources, as in Belize and El Soconusco in Mexico. Although continual reference has been made to these early villages as agrarian societies based on maize cultivation, stable isotope studies indicate that at least for El Soconusco, the diet of these first villages was not based on maize but on a mixed diet.

Complex Societies and Agricultural Intensification

Agricultural intensification with the accompanying increase of parcel productivity, whether through increased use of human labor or the introduction of more productive crops, is considered an improvement resulting from the use of applied technology or increased land quality through the incorporation of compost, moisture, or other means that involve increasing the total annual productivity (Scarborough 2012). Although it has generally been thought that demographic pressure was the cause of intensified production, with the data presently available, it is not possible to define whether the intensification observable in the Late Archaic (5,500–3,500 BCE) is the cause or the consequence of the demographic increase. This uncertainty is due to the scant nature of data on domestic contexts for this period. It is certain that one sees the accelerated diffusion of a mode of subsistence based on an extensive slash-and-burn agriculture beginning in 5,500 BCE, beyond simply the small-scale horticulture that is observed during the first half of the Archaic period (8,000–5,500 BCE).

The change from an extensive system of agriculture, such as slash-and-burn, to the various systems of intensive agriculture (including raised fields, drained fields, terraces, *camellones*, *chinampas*, and island beds) appears to be associated with demographic growth during the apogee of Mesoamerican cities and is documented at least since the Late Pre-Classic; however, this change is documented principally during the Classic and the Post-Classic. The implementation of aerial surveying in Mayan lowlands since the end of 1960 has allowed the identification of raised fields and canals on a large scale in the center of Veracruz, the Candelaria River in Campeche, and the north of Belize (Sluyter 1994). The increase in population of the larger political centers of the Post-Classic, such as those of the Aztec and Tarasco empires, required the systematic implementation of systems of intensification (*chinampas* for the Aztecs and lake-margin fields and extensive terracing for the Tarascan) and greater organization of work and the control of a large body of workers for carrying out hydraulic projects. In the Valley

of México *chinampas*, the Aztec state played an important role in developing dikes to separate saltwater from the lake. These hydraulic systems and agricultural techniques, such as the use of chinampa, amazed the Spanish conquistadores when they arrived.

International Perspectives

Although research on cultural ecology and systemic models has dominated studies on subsistence strategies for a long time, particularly with respect to the change from appropriative societies to food-producing societies, there has recently been a return to models based on the study of agency, phenomenology, and Marxist theory as alternatives that allow for recognizing the internal causality of such societies. However, studies remain lacking that would allow broadening the empirical data with which to support the various theoretical proposals.

In the case of hunter-gatherer groups, although theoretical proposals continue to be strongly deterministic in an ecological sense, mainly regarding models of the "optimal foraging" type in which hunters are viewed as inevitably destined to maximize energy resources and minimize risks (Bettinger 1991), there is a growing interest in evaluating the internal causality of these societies by assigning a more active role in historical processes, rather than simply viewing them as having a passive attitude (or, at most, reactive) where "if the medium changes, the society changes."

Regarding early agriculture and the origins of domestication, the demographic and climatic change models used for the Old World do not appear to be applicable to Mesoamerica, but consensus does not appear to exist in this respect. However, two models for the development of agriculture have been developed, with one being associated with lowlands and the other with highlands. To evaluate these models, research has been reinitiated over the last decade, allowing further empirical data to be obtained.

The author of this entry takes a social dialectical position against ecological determinism as a basis for explaining the principal changes in the modes of life of Mesoamerican societies, assuming that the principal force for change is the contradiction engendered within the communities and between the communities and their environment. The various means of resolving these contradictions are provided by specific subsistence strategies and the social and political organization of human groups that inhabited various ecosystems in Mesoamerica.

Future Directions

The study of pre-Hispanic subsistence in Mesoamerica has made great strides, beginning in the second half of the twentieth century, particularly regarding theoretical and methodological developments concerning its study. The clear trend toward the greater specialization of researchers has required collaboration in investigative networks and multidisciplinary projects, which has allowed the integration of various types of data in specialized publications, although a greater dissemination of these results to the non-specialized public remains lacking.

The development of new dating techniques that allow the dating of small samples has allowed us to register botanical materials directly and to obtain greater precision in the chronology of the initial peopling, domestication, and early agriculture. Furthermore, disciplines such as paleoethnobotany and geoarchaeology allow a better understanding of the geological and human processes linked to the creation of archaeological sites and their transformation, and an increasing number of studies use this type of focus.

Recent studies indicate greater antiquity for the processes of plant domestication in Mesoamerica, with certain dates indicating that the first domestications took place at least 10,000 years ago. The development of new techniques that allow the recovery of botanical micro-remains directly from soils, lithic artifacts, and dental calculus has allowed important data on ancient subsistence to be obtained, and new techniques are constantly being developed that permit the recovery of paleoethnobotanical information even in tropical zones in which botanical macro-remains are poorly preserved.

Regarding the first settlers of Mesoamerica, unfortunately, the trend continues to be a focus on the study of typology and the establishment of chronological sequences, which are sometimes unreliable because it remains common to date surface materials based on typology alone. Multidisciplinary studies are required to obtain greater knowledge regarding the subsistence of these first settlers and to obtain a larger number of reliable datings of the contexts.

Finally, the data on subsistence for the later periods of Mesoamerica, beginning from the appearance of the first ceramic villages, contrasts with data available for older periods linked to hunter-gatherers and incipient agriculturalists, which is scant and fragmentary. Thus, a new generation of researchers interested in the preceramic period is needed to increase our knowledge of this early period.

Mesoamerica's Archaic Period

Robert M. Rosenswig
Department of Anthropology, University at Albany – SUNY, Albany, NY, USA

Geographical and Cultural Overview Essays

Introduction

Willey and Phillips (2001 [1958]: 104–107) long ago struggled with a precise, inclusive definition of the New World's Archaic period. According to convention (today as when Willey and Phillips were writing), Mesoamerica's Archaic period begins when Holocene epoch warming reached modern conditions resulting in people exploiting a wider range of resources (~10,000 cal. BP), including plants that caused a wider range of stone tools to be used to process them. This period then ends once sedentary, ceramic-using, food producers are documented after ~4000 cal. BP. However, subsistence practices, residential mobility, and container technology are each continuous variables that do not necessarily co-occur, and so, their use to define the Archaic period does not necessarily allow for a clean cleavage from the earlier Paleo-Indian or subsequent Formative periods.

The Pleistocene-Holocene transition corresponds to the appearance of the earliest domesticated plant in Mesoamerica – the squash (Smith 1997). Therefore, 10,000 cal. BP provides a simple border to define the beginning of the Archaic period and what Smith (2001a: Fig. 7) terms the beginning of "low-level food production with domesticates." This date could be moved earlier as older cultigens are documented, but the beginning of the Holocene provides a convenient epochal transition point. The lifestyle of these early inhabitants of Mesoamerica was, however, little different than their pre-10,000 cal. BP ancestors that were not cultivating squash.

There is considerably more information for the end of the Archaic period. However, rather than creating a clear division from the following Formative period, the more detailed picture complicates matters. Researchers now argue that there is no clear distinction that occurred with the first sedentary, ceramic-using villagers in terms of either the foods consumed or their food processing tools (e.g., Blake 2006; Clark et al. 2007; Arnold 2009; Rosenswig 2012a, b, 2015; Killion 2013).

Adaptive variability is a significant factor when defining the end of Mesoamerica's Archaic period. The earliest ceramic-using villagers continued to have a nonagricultural adaptation during the fourth millennium BP (i.e., the Early Formative period). There is growing evidence that a significant increase in the reliance on domesticated foods occurred after 3000 cal. BP and that prior to this, it is more accurate to speak of horticulture (see Rosenswig 2006a: 347–348). Low-level food production (aka horticulture) characterizes the Early Formative period, and so, if we were to use intensive agriculture as the defining characteristic to end the Archaic period, then this change would only occur with the Middle Formative period beginning at 3000 cal. BP (Rosenswig et al. 2015). Many of the archaeologists who study Mesoamerica would not be comfortable with ending the Archaic period at 3000 cal. BP. For the purpose of this entry, I end the Archaic period with the first evidence of ceramic use at 4000 cal. BP (following Stark 1981 and others). However, ceramic use is first documented in the Maya zone of Mesoamerica only at the beginning of the third millennium BP, almost a 1000 years after they are recovered from most other regions (Clark and

Mesoamerica's Archaic Period, Fig. 1 Map of Mesoamerica with regions and sites mentioned in the text

Cheetham 2002). This means that the Archaic and Formative "periods" can be said to have coexisted in Mesoamerica during the fourth millennium BP (Rosenswig 2010: 34–38, 2011). The term Archaic is therefore not strictly temporal and variability during the fourth millennium BP implies a mosaic of adaptations and technologies as one form of adaptation gave way to the other.

In this entry, I focus primarily on evidence of the Archaic period from the Tehuacán Valley, the Valley of Oaxaca, the Soconusco, and northern Belize (Fig. 1). These four regions provide the most completely documented archaeological evidence of Archaic period peoples in Mesoamerica. As the first two regions are in the arid highlands and the latter two in the tropical lowlands, these examples also provide geographical diversity. I end the entry with a brief discussion of the end of the Archaic period and some directions of future research in which to better understand (1) how the so-called 4.2 ka BP event (referred to here as the 4200 cal. BP Event) of global drying impacted Mesoamerica and (2) how a mix of sedentary and mobile subsistence strategies may have created a mosaic of different adaptations during the fourth millennium BP.

Highland Evidence

Tehuacán Valley

Work undertaken by MacNeish and colleagues in the Tehuacán Valley set the agenda for the study of the Archaic period in Mesoamerica (MacNeish 1964; Byers 1967; MacNeish et al. 1967; and see Flannery 2001). The Archaic-era phases defined in the Tehuacán Valley have been the source of intense scrutiny and controversy over the past decades. Reassessments have been fueled by direct dating of the plant remains that MacNeish used to reconstruct Archaic-period subsistence practices. In most cases, dating of domesticated plants indicate that they were more recent than originally claimed. The maize recovered from early levels at San Marcos and Coxcatlán caves was clearly domesticated (Benz and Iltis 1990) and initially dated by stratigraphic association to before 7000 cal. BP. However, direct dating of six cobs produced results dating to ~4700 cal. BP and more recent (Long et al. 1989) – the end of Late Archaic period. Equally importantly, when domesticated beans from Tehuacán were directly dated, they turned out to be from the beginning of the Late Formative period at 2300 cal. BP (Kaplan and Lynch 1999; and see Smith 2001b).

Smith (2005) has reassessed the earliest domesticates and stratigraphic integrity of Coxcatlán cave based on 71 dates (both traditional radiocarbon and AMS dating of botanical remains) and established the extent of stratigraphic mixing. He concludes that post-depositional disturbance was a problem in the west half of the cave (only 6 of 27 dates [22%] fall in the expected range) but the east half of the cave was more intact (where 30 of 43 dates [70%] fall in the expected range) (Smith 2005: 9443). Importantly, 25 of the 34 AMS dates (i.e., 74 %) obtained by directly dating domestic plant remains fell outside their expected range based on published phase association of the deposits from which they were found.

The Tehuacán remains are nevertheless repeatedly employed by those who want to study the origins of crops such as maize. For example, Benz and Long (2000) calculated evolutionary rates of maize based on the morphological characteristics of 26 cobs from San Marcos and Coxcatlán caves (and see Long and Fritz 2001; MacNeish 2001a). The Benz and Long (2000) study dates evolutionary change by stratigraphic association, and so, in his taphonomic assessment of the Coxcatlán cave stratigraphy, Smith (2005: 9443) concludes that such "time-sensitive analysis of rates of evolutionary change is rendered meaningless." The most desirable solution to the problem of relying on too little data from too few sites would be to excavate more Archaic-period sites so that stratigraphic mixing at a single site does not impact our understanding of this period so severely. Despite its faults, the Tehuacán project still provides a significant contribution to the surprisingly limited amount of basic archaeological data on the Archaic-period record of Mesoamerica.

Often forgotten from the race to document Mesoamerican's earliest domesticates is the broader cultural context provided by the archaeological record. In Tehuacán, the most dramatic increase in domesticated plant use occurred at 3000–2750 cal. BP, the beginning of the Middle Formative period at the end of the Ajalpan phase (MacNeish 1967: Fig. 186 with revised dating from MacNeish 2001b). Due to his reassessment of the Coxcatlán cave stratigraphy, and the direct dating of domesticated plants, Smith (2005) reports that: "domesticated plants represent ~45% of the food plants recovered from ceramic contexts and only 2% of the plant assemblage from preceramic cultural zones." The virtual absence of domesticated plants from Archaic-period deposits requires us to accept Farnsworth et al.'s (1985: 114) alternate hypothesis of their carbon and nitrogen isotope analysis: that during the Coxcatlán phase there was an increased consumption of wild grasses and the animals that ate them. Direct dating has consistently pushed the age of domesticates from the Tehuacán Valley to more recent times.

MacNeish's (1964) model of dry season microbands and rainy season macrobands painted a picture of progressive increase in sedentism due to reliance on domestic plants so that people spent more time living in larger communities and less time foraging in small groups for wild resources. While the details and stratigraphic integrity of MacNeish's excavations have been questioned (and therefore new dating makes the timing of these changes more recent), his model of the interplay between residential mobility, group size, resource scheduling, and reliance on domesticated plants remains useful for understanding changes occurring in this arid, highland environment during the Archaic period.

Valley of Oaxaca

Equally important as the Tehuacan project in defining the research agenda for the Mesoamerica's Archaic period was the research program undertaken by Kent Flannery and his colleagues in the Valley of Oaxaca (Flannery et al. 1981; Flannery 1986; Marcus and Flannery 1996: Chapters 4 and 5). Flannery's (1968, 1973, 1986: 19–28) influential model posited the Archaic period shift to seasonal scheduling was based on the unreliability of foods that provided the driving force that encouraged food production as a risk buffering strategy.

Early Archaic period populations are estimated at 75–150 people for the entire Valley of Oaxaca and documented only from a few microband sites (Marcus and Flannery 1996: 53). Excavated in 1966, the site of Guilá Naquitz was occupied

between 10,000 and 8500 cal. BP at least six times during the summer and fall months (Flannery 1986). Deer and rabbit were eaten, as were acorns, maguey, cactus leaves, and a variety of fruit. Unlike the Coxcatlán case, Smith's (1997) direct dating of botanical remains and taphonomic evaluation (Smith 2000: 20–27) document no more stratigraphic mixing of the Guilá Naquitz cave deposits than those originally reported by Flannery (1986: 65–95, 175–176).

Botanical remains from Guilá Naquitz have contributed to understanding the diet of Mesoamerica's inhabitants during the Archaic period. Piperno and Flannery (2001) report AMS dates from two maize cobs recovered from Guilá Naquitz that provide the earliest directly dated macrobotanical examples of this domesticate in Mesoamerica at 6300 cal. BP. Benz's (2001) description of these early (and tiny by modern standards) ears of corn is having two rows of cupules and non-disarticulating rachis that still make them dependent on human propagation. In addition to the early maize, there is also evidence of teosinte pollen at Guilá Naquitz, Gheo-Shih, and Cueva Blanca (Marcus and Flannery 1996: 67). Using nine assays, Smith (1997) reports directly dated squash remains from Guilá Naquitz to 10,000–8000 cal. BP. Morphological analysis of this squash reveals thicker rinds, larger peduncle diameter, and one with an orange color, which are all characteristics consistent with domestication. Wild bean species were consumed by the inhabitants of Guilá Naquitz, and while there is no evidence that they were domesticated (Kaplan 1986), there is circumstantial evidence to infer higher density of wild beans near the cave entrance was due to cultivation (Flannery 1986: 15). Along with the redating of beans from Tehuacán (Kaplan and Lynch 1999), it seems that wild beans may have been used to produce a complete protein, but that active control of this plant was not an early piece of the nutritional puzzle during the Archaic period (Smith 2001b). Squash, maize, and beans were each added independently to the Valley of Oaxaca diet and thus must have each been adopted for their own qualities and not as an agricultural package reflecting a new subsistence strategy. Further, together squash, maize, and wild beans never accounted for more than 4% of the plant remains deposited at Guilá Naquitz (Flannery 1986: 315).

Gheo-Shih was an open-air site not far from Guilá Naquitz that was occupied multiple times in the Middle Archaic period during the summer months (Marcus and Flannery 2004). The site is best known for two parallel lines of stones 7 m apart that could have functioned as a dance floor, a ball court or a road. The inhabitants of Gheo-Shih numbered 15–25 and ate only wild foods (Marcus and Flannery 1996: 59). Variability during the Early and Middle Archaic periods between the cave site of Guilá Naquitz and the open-air site of Gheo-Shih highlight the fact that during different times of the year and in different locations, different foods were being consumed. An important point when interpreting the ephemeral evidence from these sites is that before intensive agriculture and long-term storage, diet was not constant or stable. People could have seasonally exploited domesticates and still have foraged exclusively for wild resources during significant portions of the year.

Our only glimpse of the Late Archaic occupation in the Valley of Oaxaca comes from Level C at Cueva Blanca. Based on these data, Marcus and Flannery (1996: 61) propose that the inhabitants of the Valley of Oaxaca shifted from a foraging to a collecting strategy (sensu Binford 1980) at the end of the Late Archaic period. Cueva Blanca Level C is proposed to be the remains of an all-male deer hunting party who would have brought their kill back to a base camp on the valley floor.

Recent Evidence from the Chiapas Highlands, Honduras, and the Balsas Region of Guerrero

There are a number of other Archaic-age sites in Mesoamerica that warrant mention due to new evidence. The first is Santa Marta Cave in highland Chiapas that was originally tested by MacNeish and Paterson (1962) in his pursuit of dry caves with well-preserved early levels. Recent excavations by Guillermo Acosta Ochoa (2008; Acosta Ochoa and Pérez Martínez 2012) have not produced macrobotanical remains, but

microbotanical evidence documents economic species such as maize and cacao back to 8000 cal. BP.

Discoveries in the dry El Gigante rockshelter in southwestern Honduran highlands are well preserved, and Timothy Scheffler et al. (2012) documented an Archaic period occupation by 7000 cal. BP that includes storage pits. Excavations in the rockshelter have uncovered aceramic levels with faunal and botanical preservation. Recent botanical analysis from this rockshelter indicates human selection resulted in increased maize productivity between 4200–4000 cal. BP (Kennett et al. 2017). Ten maize cobs recovered from El Gigante were directly dated and indicate that at this time, a significant selection for increased yield as they all have 12–14 rows of kernels (Kennett et al. 2017), although they exhibited a great deal of morphological variability.

Evidence also comes from the Xihuatoxtla rockshelter from the Balsas region in Guerrero (Piperno et al. 2009; Ranere et al. 2009). A 1-m deep sequence of occupation was documented with lower levels dated to 8700 cal. BP. Fauna and macrobotanical remains are not preserved from this site, but ground and chipped stone tools are present, along with starch and phytolith evidence of maize and squash.

Lowland Evidence

Soconusco

The work of Barbra Voorhies (2004, 2015) and her colleagues provide the majority of what is known of the Archaic period occupation of the Soconusco region in southern Chiapas. These data are from excavations at six shell mounds that were made of marsh clams and periodically used, based on an absence of house floors or hearths as well as a low diversity of tools and faunal species.

The Archaic period in the Soconusco is defined by the Chantuto A (6000–5000 cal. BP) and Chantuto B (5000–1900 cal. BP) phases (Blake et al. 1995; Voorhies 2004). Chantuto A is known from the single shell mound site of Cerro de las Conchas which is located in a mangrove-estuary environment and produced a number of radiocarbon dates, but little information pertaining to subsistence activities is currently available. The Chantuto B phase is known from five estuary shell mound sites and the upland site of Vuelta Limón. The estuary sites are interpreted as seasonal resource procurement locales and Vuelta Limón as a base campsite (Voorhies 2004; Kennett et al. 2006).

The site of Tlacuachero is a Chantuto B period shell middens (Voorhies 2015). A large, prepared clay surface was encountered with post holes forming two oval structures, one measuring 4 × 8 m (Voorhies 1976: 38; Voorhies et al. 1991). This site was seasonally occupied to procure clams, fish, turtles, and other marine resources, and the tools recovered included milling stones and hammer stones. In addition, 57 obsidian flakes were found at the site and trace element analysis indicates that these Archaic-period peoples were obtaining obsidian from highland Guatemala (Nelson and Voorhies 1980). Two burials have been excavated from the Tlacuachero site, and one of them, an adult male, had extremely worn teeth (Voorhies 1976: 67). Isotopic analysis of these burials indicates a reliance on C4 plants, which includes maize, teosinte, and other grasses (Blake et al. 1992). However, Blake et al. (1995: 167) have suggested that these isotopic results may be due to high levels of consumption of marine resources, and one may actually date to the Classic period (Clark et al. 2007: 31). Phytoliths have been analyzed from the Tlacuachero midden, and a sediment core indicates that a similar mangrove environment prevailed during Chantuto times. Unfortunately, no identifiable pollen was recovered from the site nor was phytolith data pertinent to economic behavior (Micheals and Voorhies 1999: 48). Analysis from Vuelta Limón indicates that forest elements dominated the phytolith assemblage but indicators of disturbance, such as grasses, are also present.

Kennett et al. (2010) argue that "pre-pottery slash and burn farmers" were operating on the Pacific coast of Chiapas by almost 8000 years ago. This interpretation is based on pollen, phytoliths, and charcoal from two cores: one collected in the Acapetahua area around the Chantuto

mounds and the other 35 km northwest up the coast near the town of Pijijiapan. Core SOCO5–3 in the Acapetahua zone documents pollen evidence of maize and that "Zone 2 (525-475 cmbs [4200-3990 cal. BP]) is marked by a dramatic but temporary increase in red mangrove pollen" (Kennett et al. 2010: 3406). The Pijijiapan core's pollen included no maize from before the Common Era, but the charcoal record shows that "very high fire activity occur [ed] between ~4300 and 4200 cal. BP, 5200 cal. BP, and between 5800 and 5600 cal. BP" (Kennett et al. 2010: 3407). Kennett et al. (2010: 3407) argue that their environmental data is "consistent with burning of agricultural fields." While swidden agriculture is certainly one possible interpretation, another is natural lighting strikes causing forest fires in an increasingly dry environment. A third potential explanation is that foragers set fire to open fields to enrich the soil and/or drive out animals they were hunting (or both). The current paucity of data precludes saying much with certainty, and each of the three hypotheses is worth exploring.

Neff et al. (2006a, b) document similar timing of forest disturbance and a late fifth to early fourth millennium BP drying period based on the six cores from the coast of Guatemala. They interpret this as the "activities of Archaic-period populations practicing shifting horticulture" (Neff et al. 2006a: 288) and further "a pattern of extensive land use by horticultural people who exploited terrestrial fauna and wild plants but also modified the tropical forest ecosystem and incorporated domesticates" (Neff et al. 2006a: 291). Neff et al.'s (2006a) interpretation of horticultural and logistically organized collectors is consistent with how Voorhies and Kennett (Kennett and Voorhies 1996; Voorhies 2004; Kennett et al. 2006) have previously interpreted their archaeological data. That ancestral maize was being used in the Soconusco by 8000 cal. BP is clear. The possibility that fields were burnt by humans at this time seems a distinct possibility. However, lacking is any evidence to support the interpretation of intensive agriculture (swidden or otherwise) being practiced at this early date.

One striking correspondence is the major disturbance period documented by Kennett et al. (2010) between 4200 and 3900 cal. BP with the 4200 BP Event, a major environmental disturbances around the world (e.g., An et al. 2005; Booth et al. 2005; Perşoiu et al. 2019) that, among other things, is used to explain the fall of many Old World civilizations (Weiss et al. 1993; Weiss 2016). This "event" lasted for ~300 years and corresponds precisely to the dramatic disturbance documented in the pollen record of SOC05–3 in the vicinity of the Chantuto sites. Charcoal from increased burning between 4200 and 3900 cal. BP is documented by Kennett et al. (2010) along the Chiapas coast and Neff et al. (2006a, b) along the Guatemalan coast. Most telling is that Kennett et al. (2010: 3407) report that burning of grasses (and not trees) is documented in their charcoal record and that these remains are due to burning that occurred upstream on the coastal plain and that the charcoal was washed downstream into the estuary were their cores were located. Dry conditions were likely exacerbated by the activities of local human inhabitants of the Soconusco who burnt newly opening grasslands. Neff et al. (2006a: 288) argue that this "was a punctuated evolutionary event associated with population fragmentation caused by a reduction in available moisture shortly after 2000 cal. BC." I return to the implications of this Soconusco environmental data, and changes in maize morphology from El Gigante, in the discussion section below.

Northern Belize

Relatively more archaeological work has been undertaken by a greater number of people in Belize than in most other areas in Mesoamerica. However, this work has not produced a clearer or more robust record of the Archaic period. Lohse (2010) reviews the Archaic period evidence from Belize. Looking for a lowland location to compare with his Tehuacán work, MacNeish (1981, 1982) began the Belize Archaic Archaeological Reconnaissance project (BAAR) and recorded almost a hundred possible sites in the northern half of the country (Zeitlin 1984). The BAAR defined a continuous sequence of Archaic-period phases that

parallel those defined at Tehuacán; however, subsequent work has shown this sequence to be untenable (Lohse et al. 2006).

The best defined Late Archaic sequence in northern Belize (as well as anywhere in the Maya lowlands) comes from work carried out at the site of Colha and nearby Cobweb swamp (Hester et al. 1980, 1996; Hester 1994; Iceland and Hester 1996). Investigators divide the Late Archaic into an Early Preceramic (4500–3900 cal. BP) and a Late Preceramic period (3500–2900 cal. BP) based on the radiocarbon dates (Hester et al. 1996; Iceland 1997). Two formal, superimposed lithic production areas were documented at Colha – a lower surface (Zone C) of Archaic date was found with evidence of constricted uniface production (debris and refits) under another prepared surface (Zone B) with burin spall cores and other diagnostic Middle Formative lithic production debris (Hester 1994: 3; Hester et al. 1996: 47). At Colha, Operation 4046, Zones C and D both contained ". . . large amounts of patinated lithic material including constricted unifaces, biface and macro-blade fragments, and debitage, but no ceramics. . ." with associated dates that range between 4900 and 3000 cal. BP (Hester et al. 1996: 45).

Colha is located at the north end of an extremely high-quality chert-bearing zone that was extensively utilized from Archaic times up until Spanish contact. Numerous highly patinated flakes, large blades, projectile points, sandstone bowls, and constricted unifaces have been identified in a handful of sites in northern Belize, including Colha. Lowe points have been tentatively dated to 6500–5900 BP based on associated radiocarbon dates (Kelly 1993: 215), and this tool type is the primary archaeological characteristic of the Early Preceramic period (see Stemp and Awe 2013; Stemp et al. 2016). Constricted unifaces are associated with the Late Preceramic and have been identified as woodworking adzes (Gibson 1991), but could have also been used as digging tools, as suggested by experimental and microwear studies. Both activities are consistent with a horticultural adaptation.

Mary Pohl et al. (1996) undertook a paleoecological program of coring and excavations at a number of swamps in northern Belize and have run over 40 radiocarbon dates. They documented maize and manioc at Cob swamp by 5000 cal. BP. Yet tree pollen indicates that these cultigens were grown in high tropical forest with minor disturbance (Pohl et al. 1996: 363). However, John Jones' (1994) pollen analysis indicates that after 3500 cal. BP, forest disturbance became extensive with significant increases in maize and charcoal remains. The lithic assemblage from Pulltrouser Swamp is similar to that at Colha, with the diagnostic complex of unifacially worked macroflake tools (Pohl et al. 1996: 366) and dates that place a constricted uniface found there between 3300 and 3000 cal. BP (Bower 1994: 279).

Environmental data and corroborating lithic assemblages from northern Belize suggest that horticultural societies were using a specialized lithic technology to clear and plant crops for over a millennium and a half prior to the first use of ceramics in the region. Forest disturbance is also documented at this time in the Petén Lakes (Vaughan et al. 1985) and the Petexbatun (Johnston et al. 2001: 158–159) regions of lowland Guatemala. Environmental evidence suggests that humans were having an increasing impact on environments in the Maya lowlands by 4500 cal. BP. However, there is still little archaeological evidence from this time period pertaining to settlement patterns, social organization, or variation in economic activities.

After inadvertently encountering Archaic period occupation at multiple locales along the Freshwater Creek drainage in northern Belize (Rosenswig and Masson 2001), these deposits were tested at Progresso Lagoon (Rosenswig 2004; Rosenswig et al. 2014). At Caye Coco, approximately 150 sq. m of distinctive orange soils containing patinated, Archaic-period lithics were documented near two pit features and a single posthole. We also found two hammerstones. Excavations at the nearby Fred Smith site on the western shore of Progresso Lagoon, facing Caye Coco, produced many more heavily patinated tools from orange soils, including a variety of expedient and formal bifaces, unifacial tools made from macroflakes, and abundant utilized flakes. Radiocarbon assays of carbon in the orange soils at Caye Coco date to

the Middle Archaic period. Two dates reported by Zeitlin (1984) collected by the BAAR project in an orange soil stratum at Betz Landing, 500 m south of the Fred Smith site, are from the early fourth millennium BP (see Rosenswig et al. 2014: Table 1). From seven patinated tools recovered from five sites along the Freshwater Creek drainage, Pearsall documented starch grains of domesticated maize, chili peppers, squash, manioc, and wild beans (Rosenswig et al. 2014). Different lithic reduction patterns at island and shore sites provide a glimpse of regional land-use patterns; tools were broken and resharpened on islands where crops were planted, but they were made at camps on the shore (Rosenswig et al. 2014: 318). The Archaic-period occupation in the Freshwater Creek drainage seems to be extensive and a renewed campaign of fieldwork is planned.

Discussion

The fragmentary nature of data on the Archaic-age sites does not provide a representative picture of the range of peoples who lived at this time or the variety of their adaptations. Writing of the Oaxaca and Tehuacán records of food production, Buckler et al. (1998: 161) observed that: "While the best-reported and most extensive archaeological sites in Mexico occur in these semiarid regions, the ecological zone was unimportant in the domestication of most Mexican crops." More is known now than 20 years ago, but the progress has been slow going. This is undoubtedly due in part to the relatively low population density of Archaic period inhabitants of Mesoamerica as there were simply fewer people whose remains are left to encounter compared to their Formative and Classic period descendants. Equally as important though is the surprisingly small number of archaeologists who are interested in searching for and excavating sites from Mesoamerica's Archaic period.

I end this entry by briefly focusing on two observations. First, that the end of the global 4200 cal. BP Event corresponds to the beginning of the end of the Archaic period. Second, that during the course of the fourth millennium cal. BP, Mesoamerica was occupied by a mosaic of peoples following both "Archaic" and "Formative" adaptations. These are both empirical observations that have significant implications for how Mesoamerica's Archaic-period adaptation is understood.

The 4200 Cal. BP Event and Mesoamerica

Much discussion of drought in Mesoamerica has focused on the Classic period Maya collapse. A frequently cited synthesis of worldwide collapse published two decades ago discusses the Akkadian and Maya collapses, one after the other despite their separation by 3000 years (de Menocal 2001). More relevant would have been to compare the effects of a single drought period on different parts of the world and to peoples with different forms of sociopolitical organization. The 4200 BP Event appears to have played a part in the collapse of integrated, hierarchical societies in the Old World that depended on agriculture to sustain the political and administrative organization (Weiss 2016). But what about the effects of this global drying period on early horticultural peoples such as those in Mesoamerica?

No other Mesoamerican archaeologists I am aware of discusses the 4200 BP Event in print (but see Rosenswig 2006b, 2015). However, this global, centuries-long environmental disturbance caused dryer conditions ended precisely when ceramic containers were first adopted at 3900 cal. BP. Drought conditions before this time are clearly documented at eight different sites across the US Midwest using a variety of high-resolution environmental reconstructions (see Booth et al. 2005). For example, between 4200 and 4000 cal. BP, the pollen and charcoal analysis of South Rhody peatland in northern Michigan documents an increase in frequency and intensity of wildfires, a disturbance of forest vegetation, and a drop in the water table to its lowest point in the past 5000 years (Booth et al. 2005: 322). An abrupt, centuries-long period of deforestation also began at 4200 cal. BP in Italy (Drysdale et al. 2006), East Africa (Thompson et al. 2002), and China (An et al. 2005) to name but a few of the rapidly accumulating cases of this global event (see Walker et al. 2018).

Neff et al. (2006a) argue that a coordinated change in forest disturbance suggests an environmental cause for changes, whereas an uncoordinated series of disturbances is more consistent with human-induced environmental change such as early horticulture. Based solely on the six cores from the Guatemalan coast, their data was inconclusive (Neff et al. 2006a). However, combined with the cores from the Chiapas coast (Kennett et al. 2010), a clearer picture emerges of an environment with less forest cover and more fires in the grasslands of the Soconusco during precisely the same two to three centuries that the 4200 cal. BP Event is documented globally.

Add to this the timing of morphological changes to maize document in Honduras at the El Gigante rockshelter (Kennett et al. 2017) and evidence is emerging for a climate-induced subsistence change occurred in Mesoamerica at the end of the fourth millennium BP. Currently, the earliest two-row distichous maize cob is documented in the Oaxaca highlands and dates to 6300 cal. BP (Piperno and Flannery 2001). This Oaxacan example shares domesticated characteristics (e.g., rigid rachis, paired spikelets, perpendicular-oriented spikelets) with the earliest polystichous cobs from the Tehuacán valley that date to ~5000 cal. BP. Furthermore, genetic data indicate that genes controlling stems and inflorescence architecture from the Tehuacán samples resemble modern maize but genes controlling for ear shattering and starch biosynthesis were comparable to teosinte (Ramos-Madrigal et al. 2016; Vallebueno-Estrada et al. 2016). A small number of maize cobs from Tamaulipas in northern Mexico provide early evidence of increased cob size and row number occurred at ~4400 cal. BP (Smith 1997) and genetic work suggest starch productivity and protein storage allele frequency were similar to some modern varieties (Jaenicke-Després et al. 2003). As the ten 12–14-row maize cobs recovered from El Gigante date to between 4300–4000 cal. BP, this suggests significant selection for increased yield. This was also when drought-resistant maize varieties evolved and diffused in the southwest United States at ~4100 cal. BP (da Fonseca et al. 2015). Archaeological and genetic evidence thus both suggest that after initial domestication early maize did not change significantly for many millennia until approximately 4200 cal. BP when inhabitants of Mesoamerica were also readapting to an environment changed by the drought event.

It is possible to explain the contemporaneous collapse of multiple Old World civilizations as a domino effect and the result of trade and tribute networks falling apart. However, the global nature of the environmental disturbance makes even this interpretation unlikely (Weiss 2016; Walker et al. 2018). Whereas agriculturally dependent empires in the Eastern Mediterranean and the Middle East could no longer fund their political and military institutions, the end of the two to three century-long 4200 BP Event corresponds to the first adoption of ceramic containers and increased evidence of sedentary villages in the Soconusco, Oaxaca, and Tehuacán. Why would an increasingly wet environment result in decreased mobility? This is an empirical pattern in need of an explanation. In the Maya area, changes in container technology and residential mobility occurred nearly a millennium later. The reason why the Archaic period in the Maya area lasted so much longer than elsewhere in Mesoamerica, and the shift to a "Formative" adaptation did not follow the 4200 BP Event, is another pattern that begs for an explanation.

Fourth Millennium BP Adaptive Mosaic

The fourth millennium BP was a fascinating time in Mesoamerica as the Late Archaic transitioned to the Initial Formative period creating an adaptive mosaic across the region. The first ceramic-using villagers in Mesoamerica are documented at ~4000 cal. BP once the 4200 BP event ended. The earliest ceramic-using villagers appear to have been isolated local phenomena. The highland Purrón phase in Tehuacán (MacNeish 1964, 2001b) and the Epiridón phase in Oaxaca (Marcus and Flannery 1996) are known from very few sherds at single location spots, and much of the rest of the area was presumably still inhabited by foragers. In the Soconusco, sophisticated Barra phase ceramics (3900–3700 cal. BP) are known from a handful of sites on the coastal plain (Lowe 1975; Blake et al. 1995). Then,

during the course of the fourth millennium BP, ceramic-using villagers expanded into most regions of Mesoamerica (Clark and Cheetham 2002).

I have proposed that the fourth millennium cal. BP Mesoamerican consisted of an adaptive mosaic where ceramic-using villagers began as an anomaly whose numbers then progressively increased among the "Archaically-adapted" foragers who occupied most of the region (Rosenswig 2010: 13–46; 2011). Along with early villagers, less sedentary peoples were probably quite common in Mesoamerica at this time (Kennett et al. 2006: 104–105; Neff et al. 2006a: 308; Rosenswig 2006a, 2015; Arnold 2009; Blake and Neff 2011; Inomata et al. 2015). During the course of this millennium, sedentary, food-producing villagers went from being an anomaly to the most pervasive settlement/subsistence strategy across Mesoamerica. The implication of this proposal is that when studying early sedentary Mesoamerican peoples, it is worth considering the distinct possibility that other groups coexisted – especially those with greater residential mobility, less ceramic use, and/or subsisting on greater quantities of wild resources. Regional landscapes often form mosaics of adaptive strategies that are dynamically integrated and regulated by fluctuating environmental and social conditions (e.g., Stahl 2004).

The Archaic-Formative transition was not a temporally uniform occurrence in Mesoamerica. One of the better known, nonsedentary, adaptations that persisted throughout the Early Formative period was that of the inhabitants of northern Belize where ceramic use and village life were only adopted ~3000 cal. BP (e.g., Lohse 2010). One reason why the preceramic peoples in this area are known is that they lived near a source of high-quality chert which they used to make distinctive tools (e.g., Rosenswig et al. 2014). Other fourth millennium BP nonceramic-using peoples have likely gone undocumented in much of Mesoamerica – especially those who relied on more perishable forms of material culture. Philip Arnold (2009) also describes the variability of Early Formative adaptation on the Gulf Coast and argues that semi-sedentary peoples lived at La Joya, which was only a 2-day walk from the early Olmec capital of San Lorenzo. The transition was not as simple or as sudden as many assume.

I have proposed that the inhabitants of the Soconusco, the Gulf Coast, Grijalva Valley, Valley of Oaxaca, and Basin of Mexico and other islands of cultural complexity interacted with each other over long distances (Rosenswig 2010: 34–38, 2011). And further, that together these peoples formed an archipelago of cultural complexity. The cultural islands shared more with each other than with their more mobile neighbors who surrounded them (Rosenswig 2017). This interpretation is more consistent with the available evidence than one that posits a continuous distribution of people with a similar adaptive base and employing material culture graded from one set of stylistic standards to the next over vast areas of the early Mesoamerican landscape. Acknowledging the presence of peoples with less sedentary adaptations should impact the ways in which we model both local and interregional interaction in Mesoamerica during the fourth millennium BP. The persistence of nonsedentary peoples further emphasizes how stable and long-lasting Mesoamerica's Archaic period adaptation was.

Conclusion

Mesoamerica's Archaic period – defined by peoples without ceramic containers dependent on a mix of wild and domesticated foods – lasted for a longer time than that of all villages, states, empires, and industrial societies combined. As the inhabitants of Mesoamerica followed a stable Archaic adaptation for 6000–7000 years (10,000–3000/4000 cal. BP) of the Holocene, what needs to be explained is when and why change occurred at all and why such change was so slow and patchy. To understand the final millennium (i.e., 4000–3000 cal. BP), we need to assume that mobile foragers lived alongside newly emerging villages (see Rosenswig 2011) and explain why the inhabitants of certain regions – particularly the Maya area – maintained the long-lasting Archaic adaptation so persistently. Future research into the end of the Archaic

period will need to address what it was about environmental amelioration at 4000 cal. BP or 3900 cal. BP (after two or three centuries of drought) that would result in people reducing their level of residential mobility, settling in villages, and adopting ceramic containers.

Metal Detecting in Archaeology

Douglas D. Scott
Social and Behavioral Sciences, Colorado Mesa University, Grand Junction, CO, USA

Introduction

The association of metal detecting with relic hunters has almost made the metal detector synonymous with site looting and is perhaps one of the reasons metal detectors have been underutilized by professional archaeologists

(Connor and Scott 1998; Ferguson 2013). Metal detectors are inexpensive and effective remote sensing devices that should become part of the basic tool kit of archaeologists working at sites where metal artifacts are likely to be a part of the site assemblage. The primary difference between relic collecting and site looting and the use of metal detectors as legitimate archaeological tools is simply the manner of application. Metal detectors find metal objects just as a shovel tests or test units might be used to discover a site's content, depth, or boundary. In archaeological applications the metal detector inventory process, coupled with precise and accurate recording techniques, is a valid and useful field survey technique (Gregory and Rogerson 1984; Dobson 1995; Hesse 2000; Sutherland and Holst 2005; Banning et al. 2006; Boon 2013.

Key Issues/Current Debates/Future Directions/Examples

Today, the use of nondestructive and nonintrusive methods of archaeological investigation is ingrained in the discipline, and archaeologists have turned increasingly to methods of remote sensing for initial site investigation (Das et al. 2000; Espenshade and Severts 2016). The metal detector is a remote sensing archaeological tool, a handheld, near surface in-phase conductivity meter. All metal detectors have a similar basic configuration that includes a handle, search coil, cable, and a metal box that houses the battery and electronic circuit board (control housing and memory).

The control housing and metal detectors have four basic technologies in which metal detectors function:

1. *Continuous sine wave*: this is the traditional type of technology as used in most basic detectors. These detectors are commonly known as very-low-frequency (VLF) models. Continuous sine wave detectors create an electromagnetic field which is applied to the ground in a continuous wave.
2. *Broadband spectrum (BBS)*: this method transmits in 17 frequencies simultaneously instead of just 1 in a square wave form rather than a sine wave as with VLF machines. A further improvement on this technology is full band spectrum (FBS), which transmits in 28 frequencies simultaneously. FBS has the benefit of offering superior ground cancellation and accurate discrimination at depth and over a wide variety of targets. This makes multi-frequency detectors the most versatile detectors available today.
3. *V/flex technology*: this uses state-of-the-art digital and mixed-signal components to enhance standard single-frequency technology. The advantages of V/flex technology are that it gives dependable performance and improved immunity to outside factors. V/flex technology also allows the detector to operate in different frequencies dependent on the coil being used.
4. *Multi-period sensing (MPS)* or *pulse induction (PI)*: this is the exclusive and patented technology. MPS technology transmits a stream of alternating short and long pulses of magnetic field into the ground, causing objects to produce a changed magnetic field of their own. This means that you can locate metal targets at far greater depth than conventional (VLF) detectors, while small targets can still be found in difficult grounds. MPS technology also aids in the accuracy of ground balance which limits the number of "ghost" or false signals. A new form of PI was introduced in 2015, Zero Voltage Technology, that enables the user to detect at depths to 1–1.5 m below ground surface.

The two basic metal detector types routinely used in archaeological metal detecting are VLF (very low frequency) and PI (pulse induction, aka MPS, ZVT). The *VLF* concept is based on sending an electrical current into the ground to determine if materials that are conductive (also called inductance) or resistive to electrical current are present. VLF technology relies on the principle of phase shift, which is the difference in timing between the transmitter coil's frequency and the frequency of

the target object. The difference is a result of its conductivity (inductance) or its resistance to electricity. An object that conducts electricity easily (inductive) is slow to react to changes in the current. An object that does not conduct electricity easily (resistive) is quick to react to changes in the current. Essentially, this means that an object with high inductance is going to have a larger phase shift, because it takes longer to alter its magnetic field. An object with high resistance is going to have a smaller phase shift.

Phase shift provides VLF-based metal detectors with its discrimination capability. Since most metals vary in both inductance and resistance, a VLF metal detector examines the amount of phase shift, using a pair of electronic circuits called phase demodulators, and compares it with the average for a particular type of metal. The detector then provides an audible tone or visual indicator as to what range of metals the object is likely to be. Depths of 30–35 cm can be reached, but 20–30 cm is the normal depth range of VLF machines.

PI technology sends powerful, short bursts (pulses) of current through a coil of wire. Each pulse generates a brief magnetic field. When the pulse ends, the magnetic field reverses polarity and collapses very suddenly, resulting in a sharp electrical spike. This spike lasts a few microseconds (millionths of a second) and causes another current to run through the coil. This current is called the reflected pulse and is extremely short, lasting only about 30 μs. Another pulse is then sent and the process repeats. A PI-based metal detector sends about 100 pulses per second, ranging from several dozen pulses per second to over a thousand, depending on the model or brand.

A sampling circuit in the metal detector is set to monitor the length of the reflected pulse. By comparing it to the expected length, the circuit can determine if another magnetic field has caused the reflected pulse to take longer to decay. If the decay of the reflected pulse takes more than a few microseconds longer than normal, there is probably a metal object at that location. The sampling circuit sends the tiny, weak signals that it monitors to a device called an integrator. The integrator reads the signals from the sampling circuit, amplifying and converting them to direct current (DC). The direct current's voltage is connected to an audio circuit, where it is changed into a tone that the metal detector uses to indicate that a target object has been found.

PI metal detectors are poor at discrimination because the reflected pulse length of various metals is not easily separated. However, they are useful in many situations in which VLF-based metal detectors would have difficulty, such as in areas that have highly conductive material in the soil or general environment. PI systems detect metal much deeper in the ground than other systems, up to 1–1.5 m.

The control housing also contains either preset, manual, or automatic ground-balancing functions. Ground balancing reduces or eliminates natural background mineralization in the soil type or types at the work area. This function allows the detector to perform with more predictable results. *Manual ground balance* gives the operator the ability to alter the ground balance to suit the various and changing ground mineralization being detected. *Automatic ground balance* – automatic ground tracking – refers to the ability of the detector to track the changes in ground mineralization and automatically adjust the ground balance to suit. This ensures perfect ground balance and full detection depth and eliminates the need for the operator to stop and manually adjust the detector as the ground conditions change. *Preset ground balance* is preset to suit a particular soil type. This obviously makes the detector limited to where it is able to be used.

The control circuits have built-in operational frequencies established by the individual manufacture. Operational frequency is measured in kilohertz; the frequency is the number of times a signal is transmitted into the ground and received back, per second. The lower the frequency used by the detector, the deeper it can normally penetrate. At low frequencies, however, the sensitivity to small targets is sometimes reduced. The higher the frequency, the higher the sensitivity to small targets, but it may not penetrate as deeply. In general, gold detectors operate at higher frequencies (to find small nuggets), while coin and treasure detectors work at lower frequencies for deeper penetration (the exception to this is

MPS-type metal detectors that are sensitive and deep-seeking simultaneously).

A final function of a machine's control circuit is the *discrimination capability*. This function varies by quality of the machine and the manufacture. Discrimination is the ability of the detector to identify the type of metal object found and eliminates the unwanted metal types. There are four basic discrimination types:

Variable discrimination: this is the most basic of discrimination types. It works like a demarcation line in the conductivity level. The level can be set by the operator, and all metals with conductivity lower than where the level is set are eliminated, and all metals with a higher conductivity are accepted.

Notch filter discrimination: if all metals were arrayed in order of their conductivity, from least conductive to most conductive, notch filter discrimination segments that array into zones or "notches," and each notch or zone can then be accepted or deleted. The number and width of the notches offered on the model of detector will determine, to some degree, how selective the detector can be at eliminating unwanted from desired targets (e.g., can tabs from lead bullets or brass items).

Tone identification: some detectors will indicate the possible ID (identity) of a target, by changing the tone of the target signal. Generally, low conductive metals will give a lower tone, while highly conductive metals will give a higher pitched tone.

Identification meter: better quality detectors today offer a meter or LCD screen, which will identify the target using as either a graphic display or numeric display specific to the brand or model. Note: the accuracy of discrimination is dependent on the repeatability of an object having the same conductivity as other samples of the same object. Man-made objects will normally be consistent in their conductivity; however, naturally occurring conductive minerals like gold will often have variations in their purity and therefore their conductivity. Soil mineralization will also have an effect on discrimination.

The last major hardware feature is coil or antenna differences. Today, the control circuits are not advancing rapidly even among different manufacturers. The changes in technology to allow greater depth, metal discrimination, and recovery are in the coil technology. There are three aspects to coil differences that are important:

Size: the size of a coil can influence the depth or sensitivity of a detector. The larger the coil, the deeper it tends to detect but less sensitivity it has to tiny targets. The smaller the diameter, the more sensitive it becomes but with less depth. Smaller coils will also be lighter and easier to control and may be chosen for their ability to negotiate difficult terrain or undergrowth.

Shape: the most common shapes of coil are the conventional solid round or circular coils, elliptical-shaped coils, and open-web coils. The main reason for change to shape is to conform to a physical requirement, i.e., the elliptical coil can be pushed around brush or between rocks easier than round coils. Open-web coils help cut through water when wading or detecting underwater. These coils are also popular for their reduced weight. Conventional round coils are often the more stable and high-performing coil.

Configuration: the three most common types of coil windings are concentric, double D, and mono loop. The difference between these coil types is the pattern the wire is wound within the coil, and configuration is one of the most important elements in coil technology.

Concentric coils have an inner circle and an outer circle wire winding. Its search pattern is cone shaped and can be useful for accurately pinpointing the target. Concentric coils tend to be noisier in highly mineralized ground and require more detector sweep overlap for thorough ground coverage.

Double D wound coils are now the preferred coils for most detecting. They give a blade- or chisel-shaped signal that covers the ground more uniformly, and once an operator becomes accustomed to the signal, pinpointing is no hardship.

Double D coils are also preferred for their superior ground-balancing ability.

Mono loop coils are a special style of coil for the MPS technology detectors. These coils have one winding of wire around the circumference of the coil, and this winding is used to both transmit and receive. The signal pattern of the mono loop coil is cone shaped, requiring more overlapping, and in extremely heavily mineralized grounds, they can be more difficult to ground balance; however, they tend to provide slightly better depth than the double D coils.

Metal Detectors in the Field

Operation of a metal detector can generally be learned quickly and easily for most VLF machines. The exceptions are the VLF multi-frequency machines and the PI machines which take many hours of experience to use in an effective manner. As with any tool the more experienced and skilled the operator, the more efficient the work and the better the results. Since the skill of the operator is one of the most important variables, many successful projects have relied on experienced volunteer detector operators. The volunteers are frequently metal-detecting hobbyists who provide their own machines; thus the project benefits from both knowledgeable volunteers and cost savings.

A successful archaeological metal detector project will require careful planning and adaptation of the methods and techniques to the specific site context. When developing a metal detector survey strategy, operator experience, soil conductivity, and the purpose of the work must be considered. One method of survey consists of three sequential operations: metal detecting, artifact recovery, and provenience recording. During metal detecting, metal targets are located and marked. A recovery crew follows and carefully uncovers the objects, leaving them in place. The recording team then plots individual artifact locations, assigns field specimen numbers, and collects the specimens.

Detector operators should walk abreast, following transects across the area to be inspected. Coils should be held as close to and as level with the ground as possible to provide maximum vertical and horizontal coverage. Each operator can normally cover an area of roughly 1.5–2.0 m with each sweep, depending on the individual's height and technique. The transects can also be varied in width to meet the needs of different sampling approaches, ranging from a random sample to a stratified random sampling. The 1.5–2.0 m sweep with a 5.0 m interval between detector operators obtains approximately a 35% sample of a study area. If necessary, the metal detector operator can cover a site in a series of more closely spaced units in order to cover up to 100% of the site.

Transect orientation can be based on any reasonable parameter, such as grid orientation or cardinal direction, as long as a systematic approach is maintained to achieve the desired coverage. Parallel transects and radial transects worked from a central point are two other methods that have proven successful and effective in meeting different site sampling needs.

In dense concentrations of metallic debris, it may be necessary to recover the targets located and then re-sweep the area multiple times to recover all the artifacts. The signal from larger metal objects may obscure the signal from other smaller or less dense targets unless the larger targets are removed from the detector field. Metal shafts of surveyor's pinflags can also obscure nearby buried targets so that a dense field of surveyor's pinflags will affect the number of targets found. Pinflags with fiberglass shafts are available and can be used to eliminate the masking problem found with metal shaft surveyor's pinflags.

Conclusion

Metal detectors can aid in the recovery of archaeological information from almost any site containing metal. Without excavation, by simply detecting a site and flagging "targets," the archaeologist can easily examine the distribution and varying densities of metal artifacts within a site. This can aid in identifying intra-site spatial patterning and in establishing site boundaries. In shallow, unstratified historic sites, which are common in the western United States, the targets can

be excavated and a sample of temporally and functionally diagnostic material quickly and inexpensively obtained. This can also be done within a structure or where structural remains are present; the detector can be used to quickly obtain information on age and function.

State of Knowledge and Current Debates

Introduction

Metallurgy is a technology for transforming metallic ores to usable metals. It is generally described as a sequence of steps (mainly mining, ore processing, fuel preparation, smelting, purification, alloying, casting, and/or hammering) and components (raw materials, means of production, skills, knowledge) (Lechtman 1976; Shimada and Craig 2013; Serneels 2017). Many systematic investigations of ancient metallurgy have been carried out (textbooks and monographs dedicated to the subject are available for the interested readers in section Further Readings), so this entry aims to provide just a glimpse into this fascinating world of minerals, metals, and past societies.

Ores are rocks, minerals, or alluvial sediments that contain metals that are considered valuable and that can be mined and processed with the technologies available at a certain time (Killick 2014). Gold, and sometimes silver, copper, lead, mercury, and more rarely iron, can be found as native metals. However, metals are mainly combined with other elements, as oxides, carbonates,

or sulfide minerals. Before 1500 AD, seven metals were known and employed as pure metals or natural or intentional alloys: gold, silver (with gold or copper or both), copper (with arsenic, tin, lead, or zinc), tin, mercury, lead (with tin), and iron (with carbon or phosphorus) (Rehren and Pernicka 2008).

The history of the development of metallurgy around the world is still a matter of debate as recent research and discoveries offer new evidence of past activities, and diffusion and innovation are discussed based on such data. However, it is established that native copper was the first metal to be hammered and annealed to obtain metal artifacts. The earliest evidence dates from the late ninth millennium BC in Anatolia, while independent copper working was developed around 4500 BC in North America. First evidence of copper was found in Iran and Serbia and dates from around 5000 BC. Iberia has also been postulated as a third area of metallurgical invention in the Old World (Killick and Fenn 2012). Gold was used for the first time in Bulgaria (4000 BC) (Serneels 2017). Hammered and smelted copper evidences from circa 3000 BP have been identified in the Andes, another independent area of invention where archaeologists have identified different areas of innovation and development in Peru, Bolivia, and Northwest of Argentina (Scattolin et al. 2010). Much later, circa 650 CE, this copper-based technology (cold-worked and lost-wax cast) was introduced possibly by maritime routes from South America to western Mesoamerica (Hosler 1994). On the other hand, iron metallurgy was developed independently in Anatolia and China around 1800 and 800 BC, respectively (Tylecote 1992; Killick and Fenn 2012) (for more information about metallurgy inception and development, see Further readings).

The metallurgical "chaîne opératoire" (Hauptmann 2007) or sequence of operations starts with the ore extraction. The mining operations and the preparation/treatment of minerals strongly depend on the geological characteristics of the ore deposit and its location, such as type of mineralization, ore grade, host rock, local topography, and accessibility, and also on the technology, skills, labor supply, and organization available at a certain time and within a specific society, besides other social and symbolic factors (Salinas and Salazar 2008; Shimada and Craig 2013; Stöllner 2014, among others). Gold placer mining in alluvial deposits, for example, requires the separation of gold dust from the sand and gravel by mechanical means, while the extraction of ores from underground mines involves more complex mining technologies and operations (draining, ventilation, light, supporting, etc.). On the other hand, native metals can be hammered (e.g., gold nuggets) or melted and cast (e.g., tiny flakes that can be consolidated only by melting, Killick and Fenn 2012), sometimes after sorting and crushing operations (beneficiation), such as grinding, washing, and handpicking. In the case of oxides, the change from ore to metal is achieved by smelting. As Killick (2014) mentioned, this smelting process can be quite simple, in shallow crucibles or shallow pit furnaces filled with ore and charcoal. Conversion of sulfide ores, however, requires a more complex operation, including a previous step to remove the sulfur as gaseous sulfur dioxide (roasting) (Goldenberg et al. 1996). The aim of the smelting process is obtaining raw metal to be treated in a later phase when it will be purified, alloyed, cast, shaped, remelted, hammered, and/or decorated until the final product (metal object) is ready (Hauptmann 2007).

Each of these operations involves specific materials, tools, installations, intermediate and final products, and waste. Figure 1 summarizes the steps of the metallurgical chain and the material evidences of each activity. In the analysis of these operations, researchers understand that the specificities of the entire process are controlled by technical and physicochemical constraints and also by cultural factors and choices.

Archaeometallurgy

Archaeometallurgy can be defined as a subfield of archaeological science (see Martinon-Torres and Killick 2015) or archaeometry (see ► Archaeometry: Definition entry by Wells in this volume), dedicated to the study of metal and its production, use, and distribution, among other topics related to metallurgy in the past. Diverse research strategies, techniques, and concepts from

natural sciences, chemistry, and engineering, along with ethnohistorical and experimental approaches, are employed to address the diverse archaeological evidence found in the field and the questions proposed in relation to this complex activity.

The importance of metals in ancient societies is beyond doubt, and scholars have been interested in its study from different perspectives. At the beginning of the sixteenth century, anonymous textbooks were published in Germany to teach practical notions of mining and metallurgy. They are known as Bergbüchlein and Probierbüchlein (Sánchez Gómez 1989). By the same period, Georg Agricola published the book titled *De Re Metallica* (1556); Vannocio Biringuccio, his *De la Pirotechnia* (1540); and Lazarus Erker, the *Treatise on ores and assaying* (1574). In the Andes, for example, a priest and miner called Álvaro Alonso Barba wrote the book *Arts of Metals* (1640). Although the original purpose of these works was a practical one (to teach mining and metallurgy operations), they became great sources for later studies on these past technologies. Centuries later, at the second half of the nineteenth century, John Percy wrote about traditional techniques in metal production (Hauptmann 2014), together with the appearances of other general works on the history and development of metallurgy (Rehren and Pernicka 2008). Eminent chemists, engineers, metallurgists, and physicists in this period and during the early twentieth century centered their attention on the study of metal objects, applying the innovative analytical methods developed at the time for detecting chemical composition and metallographic characteristics. Although these first approaches sometimes overemphasized the scientific techniques in detriment of a more holistic archaeological interpretation (González 2004; Rehren and Pernicka 2008), they were a huge improvement to help scholars to understand many aspects of ancient metallurgy.

Metals have been considered evidence to understand the origins and development of metallurgical practices (Tylecote 1992). They have also been interpreted as indicators of successive stages of evolution or unilineal progress and the rise of complex social hierarchies (González 2004), following into the trap of "assuming that the initial discovery of metals would have rapidly revolutionized production and thereby transformed society" (Killick and Fenn 2012: 561).

The study of metals offers also a window for analyzing mechanisms of trade, exchange, warfare, recycling, or substitution of metals (Rehren and Pernicka 2008), as the quest for metals has been one of the most important stimuli for exploration, long-distance trade, and conquest of new lands (Killick and Fenn 2012). More recently, metals have been addressed as significative products of complex social processes. In the words of Heather Lechtman (1976: 1), a pioneer researcher in Andean metallurgy, "metal objects are, after all, the products of complex technological systems, and by limiting our investigations solely to them we tend to ignore the fundamental stages that precede the fabrication of the object itself." Moreover, Lechtman stated that "it is not just the products of that industry that concern us, nor even primarily the techniques that it employed, but the nature and organization of the work force involved, the economic and political control of resources such as ores and fuel" and the articulation with other aspects of the technology and culture of the society which produced them. Therefore, a more holistic approach to metallurgy was necessary, including not only the analysis of finished products and associated manufacturing waste but also long-term interdisciplinary researches centered in the study of contexts of metal production and use, multi-site sampling and survey, archaeometrical analysis, laboratory and field experimental archaeology, ethnoarchaeology, and comparative study of artifact collections (Shimada and Craig 2013). Although interdisciplinarity continues to be challenging for any archaeological project dedicated to the study of metallurgy in the past, this kind of research design is currently much more common than it was previously, as it is shown in Roberts and Thornton's (2014) edited volume, *Archaeometallurgy in Global Perspective: Methods and synthesis* (see Further Readings).

Studying the Metallurgical Chain

Mining Activities

Mining requires specific knowledge related to mineral properties, chemical behavior, and techniques of extraction and beneficiation (Rehren and Pernicka 2008). Alonso Barba ([1640] 1939) fully described how, for example, Andean indigenous people searched and recognized minerals according to color and brightness. This kind of written sources available for historical periods provides data regarding mining techniques and also location of known and exploited mines in the past. In many cases, it is difficult to access to the mines and conclusively identify ancient labors (Fig. 2). Geological reports on mines before new labors begin offer key information about previous exploitations, especially when recent activities have erased (almost) all the evidence of possible ancient work. Published studies on ore deposits are useful for inferring possible provenance of ore samples (Killick 2014). When existing, diverse historical published and non-published documentation through which miners informed mine discoveries and requested permission to exploit them, mining authorities were designated, disputes about mine's owning or workers supply were solved, extraction process was described and ruled, etc., combined with the study of archaeological remains, enrich our understanding of labor system, agents involved, location of mines, and chronology of exploitation, among other issues. Iconographic documentation has shown the location and characteristics of the mines, galleries, pits and installations, tools, and work scenes.

Air photographs and satellite images are also very useful for identifying workings, installations, roads, and associated talus formations (Shimada 1994), as well as the analysis of toponymy. Interviews to local informants are very helpful in locating mines and establishing a relative chronological sequence of mining development in the area (Shimada 1994). Modern geological reports are usually focused on mines considered valuable or rich according to present-day economic profit standards, underrepresenting small-scale ore

Metallurgy, Fig. 2 Gallery (**a**) and vertical pit (**b**) with stairs and walls made of rocks found in Ajedrez, Jujuy, Argentina. They probably date from colonial times (around the eighteenth century)

deposits as the ones that were probably exploited during ancient times. Another problem is that the ore remaining at present day can be not representative of the ore mined in the past (Craddock 1995). The active participation of geologists or other specialists in mine survey and ore sample recollection is especially important at this stage of research design (Shimada 1994).

Combined to the regular archaeological survey methods, geophysical methods, such as seismic surveys and geoelectrical tomography, are employed in the detection and study of ore deposits. Speleological methods of measuring are applied for mapping and describing underground mines three-dimensionally (photogrammetry, laser scanning, traditional surveying with compass and graduated arc). Core drilling is employed for sounding tailings and mining depressions or shafts. Underground excavation requires special methodology due to the characteristics of the mine (horizontal or not, presence of filling layers and mining debris) (Stöllner 2014).

The spatial analysis of mining sites is essential to understand the organization of work and a miner's daily life: settlements, accesses and roads, areas for disposal of wasted rocks, crushing and selecting ores, water management systems, and other components of mining landscape are described and analyzed.

Researchers have tried to identify which ores were used by analyzing ore minerals recovered in archaeological sites and also by indirect means, studying chemical composition of metals and slag and the distribution of ore deposits in a regional scale (Killick 2014). Earth science methods, such as those from geochemistry, ore petrology, and igneous petrology, are applied with this aim. Optical and electron microscopy (see ▶ "Scanning Electron Microscopy (SEM): Applications in Archaeology", in this volume) are employed for identifying minerals, texture, and mineralogical parameters, useful to infer the mineral association in particular locations and the sequence of deposition of the minerals. A complement in this identification process is the use of chemical analysis of individual crystals by energy-dispersive X-ray spectroscopy (EDS), wavelength-dispersive X-ray spectroscopy by electron microprobe (EPMA-WDS) – better for quantitative analysis – and X-ray fluorescence (XRF) (see ▶ "X-Ray Fluorescence (XRF): Applications in Archaeology" in this volume). X-ray diffraction and Raman microscopy are also methods for identifying minerals in an ore sample (Rehren and Pernicka 2008; Killick 2014; see ▶ "X-Ray Diffraction (XRD): Applications in Archaeology" in this volume).

Artifact remains within workings can also give important information on the technology used to extract and crush the ore. The well-preserved body of a miner or Copper Man found in Chuquicamata, Chile, in 1899 (Bird 1979), with his entire equipment (lithic hammer heads, lithic and wooden shovel, wooden sticks, bag, baskets), currently displayed in the American Museum of Natural History in New York, is an extraordinary finding, but even more modest findings of tool equipment or identification of marks in mine's walls (diffuse bruising, long thin scratches, holes, burnt rocks) can give us important information about techniques of mineral extraction (use of stone or metal tools, fire setting, blasting) and chronology (as explained in detail by Craddock 1995: 10 Table 1.1; Shimada and Craig 2013). Ethnography and experimentation have great potential for interpreting functionality through the analysis of the form of tools and wear pattern as well as, for example, the traces left by fire setting (Téreygeol 2000; Timberlake and Craddock 2013; Heeb and Ottaway 2014). Radiocarbon dating has proven to be useful in dating ancient mining, when samples of charcoal from fire setting, fragments of wood, or pieces of torches are found in the mining areas (Hauptmann 2007).

Figueroa et al. (2013: 63–64) define the daily artifacts used by miners as "mining ergology," which can be divided in two categories: mining set (working and transport of materials) and personal items. In this analysis, the authors show the variability of activities related to mining that can be approached through this kind of evidence. Moreover, ritual aspects have been addressed, for example, from musical instruments and symbolically charged items found inside the galleries (Vaughn et al. 2013) or by evidence preparation and serving of food and drink for miners. Pottery

is usually found in mining sites and can be diagnostic for relative dating, especially when there are not radiocarbon-datable materials (Shimada and Craig 2013). Its study also offers us powerful data regarding the daily life of workers, circulation of people, technical knowledge and artifacts, and other important activities as the above referred commensalism rituals. When osteological remains are available, bioanthropological studies on ancient miners focused on stress markers and biomechanical and toxicological effects are another potential analysis for improving our understanding of mining activity (Figueroa et al. 2013).

The Study of Smelting Technology

As mentioned before, smelting is generally the next step after the extraction and beneficiation of mineral ores. It aims to separate metal from slag: the waste product that results from the gangue of the ore's host rock and from fluxes added to improve the smelting process (Hauptmann 2014). Smelting sites are located usually nearby the ore deposits to avoid transporting great quantities of gangue. However, sometimes other factors were also important in choosing the location, such as availability of fuel or wind and water supply (González 2004; Serneels 2017). Spatial organization and types (and quantity) of evidences of this activity will depend, like in mining, on cultural and technical constrains (scale of production, kind of mineral, etc.). In that sense, the study of patterns of distribution in smelting sites, metal (raw lumps and spills), discarded ore, slag, installations, and instruments is essential to have a better understanding of the metallurgical operational chain, the organization and logistics of production, and, of course, the society who produced and consumed the metals, its "traditions and taboos, and varying political and economic parameters" (Rehren et al. 2007: 216; Rehren and Pernicka 2008).

Furnaces have different designs, shapes, and sizes: they can be natural or forced draft, and they can be very simple like a shallow pit, smelting basins, or crucibles, or they have a more complex structure built with clay, stone, or both (see Craddock 1995 for a detailed description of furnaces types, blowpipes, and bellows). Fuel can be in contact with the ore as in the shaft furnace or separate in different chambers, as in the reverberatory furnaces employed in medieval England for melting bronze (Tylecote 1992; Craddock 1995) and in the colonial Andes and New Spain (present-day Mexico) for smelting and refining silver from the beginning of the seventeenth century and on (Alonso Barba [1640] 1939; Cohen et al. 2009; Angiorama and Becerra 2017; Téreygeol and Cruz 2012). Their characteristics can also vary according to their functionality (only for smelting or refining or for both purposes). The choice between each type of furnaces depends on fuel and labor availability and on cultural decisions (Rehren et al. 2007). Experimental archaeometallurgy has proven to be a powerful tool for recreating past smelting and refining techniques as well as the study of historical written sources (Figs. 3 and 4). Evidences of furnaces can be found in smelting sites, along with fragments of their walls or lining. Besides ore, almost present as waste, slag, refractory materials, tuyères (tube or pipe through which air is blown into a furnace or hearth), and remains of firing material are also usually found in these sites (Hauptmann 2007).

Slag is among the most common archaeological evidence of ancient smelting, even in sites where no other type of evidence of this process remains. Slag is waste products and has a very complex composition. It mainly consists of silicates and metal oxides of calcium, iron, magnesium, phosphorous, aluminum, etc. It also includes potential reusable material and sometimes, it is still rich in metal (Hauptmann 2007). Ancient slag also includes intermediate products that contain metal such as scrap metal, casting remains, and any metal-rich slag, among others (Hauptmann 2014). Through mineralogical and chemical analysis of slag, the smelted (or worked) metal and mineral ore can be identified, as well as the characteristics of the metallurgical process, the technological skill of metallurgists, scale of operation, and social and ritual behaviors (Cohen et al. 2009; Rehren and Pernicka 2008; Hauptmann 2014, Heeb and Ottaway 2014). The "human factors as recorded

Metallurgy, Fig. 4 Drawings of furnaces employed in colonial Andes made by Alonso Barba 1939. (**a**) Spanish square furnace. (**b**) Spanish round furnace. (**c**) Indigenous furnace ("huayra"). (**d**) Refining indigenous furnace (tocochimbo), similar to the reverberatory furnace. Front and lateral view

in the slags include both short-term individual decisions affecting only single smelts, and accumulated developments affecting more fundamental parameters such as furnace design and choice of raw materials" (Rehren et al. 2007: 216). Moreover, according to Rehren and Pernicka (2008), the study of slag gives even a more complete representation of the ore and smelting conditions than metal samples, because as mentioned above, slag contains not only the gangue, mineral, and sometimes metal-bearing phases but also fluxes added, furnace wall material, fuel ash (in case ore and fuel are in direct contact), and soil sediments (sometimes especially prepared for acting as a container of the ore while smelting, as stated in historical records).

Slag can be waste products of the smelting process and also of metal melting, slag or metal remelting, refining, or metal casting (Hauptmann 2014). Each of these will have particular characteristics and can be classified as smelting, forging, and crucible slag. However, in some cases, slag analysis does not allow to identify variability in furnaces designs (Rehren et al. 2007; Angiorama and Becerra 2017). Slag identification starts in the field, describing types, amount and average size, color, texture, porosity, inclusions, weathering, etc. In the laboratory, several methods and techniques are applied for identifying chemical composition, mineralogical and metallurgical phase analysis, physical constants, age determinations, and lead isotope provenance (Bachmann 1980: 104–105; Hauptmann 2014). Slag sampling is a very important step in the research design, and it will depend on whether there is evidence of a single or multiple smelting episodes, on the distribution of the slag, etc. To obtain good results, registering the location of the sample and being consistent on where to sample are essential (Rehren et al. 2007). Analytical techniques require slag sample preparation. They can be mounted and polished or prepared as petrographic

thin sections (Hauptmann 2014). Optical microscope is used for identifying phases and their orientation and distribution. Metal or metal-bearing phases or inclusions, as well as some mineralogical phases like olivine, pyroxene, or spinel, are easily identified by the expert eye only with optical microscope. However, most of the times, given the complex composition of slags, scanning electron microscopy (SEM) and electron microprobe (EPMA) with energy-dispersive X-ray spectroscopy (EDS) and wavelength-dispersive X-ray spectroscopy (WDS) are employed for spot analysis, phase identification, and element concentration mapping (Hauptmann 2014) (Fig. 5).

Other techniques are also applied, such as X-ray diffraction (powdered sample) (XRD) or X-ray fluorescence spectroscopy (XRF) and inductively coupled plasma optical emission spectrometry (ICP-OES) for trace elements. Isotope analysis (see below) is also used to search for provenance of the ore. When present, wood or charcoal included in slag can be extracted to be dated by radiocarbon dating (Hauptmann 2014). Archaeomagnetic method and thermoluminescence are also potential techniques for dating burned features. To estimate the working temperature of the furnace, archaeometallurgists employ ternary or quaternary phase diagrams of the oxides present in slag (e.g., SiO_2+FeO+Al_2O_3 or CaO+SiO_2+FeO) (see Bachmann 1980; Hauptmann 2007; 2014).

Other important evidences of smelting operations are technical ceramics, namely, ceramics used in operations involving high temperatures, as containers of metallurgical processes (crucibles, furnaces, molds) or as intermediators for providing oxygen (tuyères). To be functional, technical ceramics need to have mechanical strength and withstand high temperatures (thermal refractory properties) and sudden temperature changes (thermal shock resistance), without collapsing or being altered. In that sense, their manufacture differs from domestic pottery, requiring other skills and materials, such as refractory clays or more numerous and different secondary inclusions or temper for improving thermal shock resistance (Martinón-Torres and Rehren 2014).

Metallurgy, Fig. 5 (**a**) SEM image of smelting slag of silver-rich lead ores from Fundiciones 2, Jujuy, Argentina. Prill of lead oxides with silver in a lead-sulfide matrix with copper sulfide phases. (**b**) Compositional map (230×) where concentrations of lead, silver, copper, and sulfur can be identified (scale from cold to warm colors indicates the increasing concentration of the element (blue, low concentration; red, high concentration). Analysis occurred at LAMARX, Facultad de Matemática, Astronomía y Física, Universidad Nacional de Córdoba, Argentina

The analysis of this kind of ceramics does not differ from the one applied in the study of archaeological pottery: macroscopic inspections and microscopical analysis of mounted and polished cross sections. Variations in the manufacture of these ceramics show different technological traditions, choices, raw material provisioning, etc. As in the case of ores and slag, the application of SEM-EDS and EPMA is very useful in the analysis of technical ceramics as well as XRD for mineralogical characterization and operating temperature estimation and ICP-OES, neutron activation analysis (NAA), and XRF for identification of chemical fingerprint and, therefore, of their possible geological source (Martinón-Torres and Rehren 2014). Technical ceramics can contain oxides related to contamination through use and metal residues, which can be analyzed as any other metal or slag sample, to obtain a better understanding of the metallurgical process involved. Molds and crucibles can also be intentionally covered by other products. For example, in the pre-Columbian Northwest of Argentina, many technical ceramics show a layer of white powder, identified as hydroxyapatite (calcium apatite with the formula $Ca_5(PO_4)_3(OH)$). It is supposed to facilitate unmolding the metal from the crucible or mold and to probably give structural stability to the walls (González 2004; Zagorodny et al. 2015) (Fig. 6). Their shapes and dimensions can show us what the metal objects looked like, key information when there is no remaining evidence of the final metallic products in the site.

Finally, the study of lake sediments, ice cores, or peat deposits for the identification of metals associated with smelting, such as lead, tin, bismuth, silver, antimony, or even copper, has proven to be a powerful tool for reconstructing chronology and intensity of metallurgical activity (e.g., Abbot and Wolfe 2003).

Metal Objects and Their Manufacture

When analyzing metal objects, as any other archaeological artifact, contextual information is basic. There is a variety of metal objects. Many of them are utilitarian artifacts like tools for fishing, sewing, mining, and working metals or other materials, used on a daily basis. Others played important roles in sacred, ritual, and/or political occasions, as accessories for decoration, power demonstration, or propitiatory ceremonies as rings, necklaces, bracelets, figurines (Figs. 7 and 8), or musical instruments (Fig. 9). For example, bells comprise 60% of the metal artifacts found in Western Mexico, and their acoustical properties may, according to Hosler (1994), have collaborated in the consolidation of emerging polities in Mesoamerican area. In this context, it is not a surprise that bells of copper and copper alloys from different areas (Costa Rica, Panama, West and Central Mexico) were deposited in the Sacred Cenote at Chichén

Metallurgy, Fig. 6 Fragment of a crucible that was reused at least three times and it was covered each time by a layer of white powder identified as hydroxyapatite. It was found in an archaeological site from Belen Valley, Catamarca, Argentina, and it dates from around the fifteenth to sixteenth century AD (Zagorodny et al. 2015)

Itzá since its primary occupation (750-1050 CE) (Cockrell et al. 2014). Metals have also been used (especially in the Old World) for military and defense purposes. Approaches to metals involve typological and stylistic studies as well as the identification of traces of use to identify functionality.

Metallurgy, Fig. 7 Anthropomorphic figurine from Inca times found in Puerta de Juella, Quebrada de Humahuaca, Jujuy, Argentina. It is made of an alloy made of gold and silver with little percentage of copper (2%) (Analysis courtesy of Mg. María Teresa Plaza). Source: object MLP-Ar-3777 from Muniz Barreto Collection, División Arqueología, Museo de La Plata, Facultad de Ciencias Naturales y Museo, Universidad Nacional de La Plata, Argentina

Archaeometallurgical studies not only have paid attention to use and distribution of metals but also to manufacture processes. Producing a metal object "requires a fine understanding of the behavior of metals and alloys, over a range of temperatures from cold to fully liquid, combined with the artistic skill required to make both the functional and beautiful objects desired by patrons" (Rehren and Pernicka 2008: 234).

Metal objects were produced employing a wide range of manufacturing techniques, according to the desired characteristics for the final product, the artisan's skill, the available material, and the metal properties (González 2004). Artifacts can be made of one pure metal but also of natural or intentional alloys. The mixture of metals modifies and generally improves some of the properties of the material (hardness and elasticity, color, decrease of fusion temperature, etc.). They can be cold-hammered to shape, with or without heat treatments. This process is called annealing and consists of heating metal above recrystallization temperature, altering its physical properties to increase its ductility and reduce hardness. Then, the metal sheet can be manipulated, cut, embossed, bended, engraved, etc., to shape the object, give relief, and draw geometrical or figurative designs, among others. Two or more sheets can be fastened one to another by rivets or other devices but also by different types of welding and soldering. On the other hand, metals can be melted and poured into a mold that can be one-piece (open), bivalve (two halves joint together), or composite (three or more pieces) depending on the complexity of the object.

Metallurgy, Fig. 8 Chisel made of a copper-alloy found in Moreta, Puna of Jujuy, Jujuy, Argentina. Source: object MLP-D25-CMM-Nº(v)8191/(r)138 from Márquez Miranda Collection, División Arqueología, Museo de La Plata, Facultad de Ciencias Naturales y Museo, Universidad Nacional de La Plata, Argentina

Metallurgy, Fig. 9 A copper bell (length = 2.9 cm) (**a**) made by lost-wax casting from the site of Tipu in Belize. It is associated with a context dating between the second half of the sixteenth century and the first half of the seventeenth century. A section of the bell was etched with ferric chloride ($FeCl_2$ with 20% HCl) (**b**) to reveal its as-cast, dendritic microstructure (red-orange areas). The metal inclusions (white spots) between dendrites emerged on cooling, as this metal was not absorbed into the dendritic areas. Field of view = 1 mm across (Images courtesy of Bryan Cockrell. Analysis occurred at UCL's Wolfson Archaeological Science Laboratories. As in Figs. 7 and 8, with profound respect to the indigenous communities who made and used this bell and others like it)

In many cases, artifacts need to be further hammered to obtain the final product. When the design of the object is even more complex, lost-wax technique is applied. The method can vary in details, especially if the final product will be solid or hollow. In general terms, a clay mold is created of a wax model, so the inner walls of the mold are the exact negative of that original model. When metal is poured into that mold, an artifact with numerous decorative details can be achieved.

Surface treatments are also used for decoration purposes. Colors and brightness have been very important properties for ancient societies. The use of certain metals and alloys could respond to the search of an object with a particular color. Moreover, metallurgical and electrochemical procedures for gilding and silvering objects were other mechanisms for obtaining the desired look. In that sense, for example, repeated sequences of hammering, annealing, and removing of surface copper oxide on copper-silver alloys produce an object with a silver-rich surface. Coatings obtained by systems of electrochemical deposition were also a solution for gilding. The process consists of the immersion of a copper sheet in a bath of aqueous solution of corrosive salts where gold is dissolved. A thin film of this metal will deposit on the copper surface. To bond the two metals permanently, heat must be applied so a solid-state diffusion of copper and gold is produced across their mutual interface (Lechtman 1984).

All these manufacture operations involve technical ceramics (furnaces, molds, crucibles, blowpipes, spoons), metal objects (chisels, hammers, handles), leather and bone implements, and stone tools. Some of them are very diagnostic of metallurgical activities, but others are also used for agricultural purposes, for example. In those cases, it is hard to distinguish functionality. Webb (2015), for example, has proposed a distinction of grinding and hammerstones dedicated to mining-metallurgical activities opposed to those dedicated to processing vegetables in Middle Bronze Age Cyprus, not only according to hardness of raw material and use-wear marks (as Craddock 1995) but also to greater number, size, and weight.

Several methods for identifying chemical composition of metal objects are employed in archaeometallurgy, most of them already mentioned in this entry: proton-induced X-ray emission or gamma emission (PIXE or PIGE), NAA, XRF, XRF with synchrotron radiation (SR), ICP-OES, ICP-MS (mass spectrometry), SEM-EDS, and EPMA-WDS. These analyses offer qualitative and quantitative data on the original composition and the current condition of metal objects (see entries in this volume). X-ray radiography and tomography are employed to reveal internal

structure of the object (Scott 2014). Selecting which method will be applied depends on many interactive factors: research aim, pre-existing dataset to compare and integrate, limits of detection, precision and accuracy of each method according to questions asked, conservation concerns (nondestructive, mild, or destructive analysis, access and transport of samples), and financial and time constraints (see Pollard and Bray 2014 for more information for selecting which analysis is more appropriate given what circumstances).

As mentioned above, two of the main research interests in archaeometallurgy have been reconstructing metallurgical production and identifying the geological origin of the metal used for manufacturing an object. Metallography has been applied since the beginning of the twentieth century to address questions regarding technologies of manufacturing and decoration. It consists of the application of microscopic techniques to identify composition, microstructural components, extent of corrosion penetration, method of fabrication (cast or work and anneal to shape), thermal history of the object, and authenticity. This analysis requires a small and polished section of the object, representative of the object or chosen to study a particular feature or area. During metallographic examination, diverse microstructure features are identified: range, size, and shape of the grains give information about fabrication operations; identification of different phases informs about ores and alloys used as well as cooling speed; heterogeneity in the sample, inclusion, porosity and corrosion products or distribution of layers, and the presence of coating, gilding, twin or slip lines, and dendrite pattern, among others, are indicators of manufacturing techniques (Scott 2014: 67, 70–71). The study of such indicators allows the reconstruction of the working history of the object, revealing the sequence of events (Rehren and Pernicka 2008) (Fig. 9). Binary and ternary phase diagrams (two or three metallic components) are employed by the archaeometallurgist together with metallography. They describe the different phases present in an alloy, taking into consideration both composition and temperature.

Regarding provenance studies (see entry ▶ Provenance Studies in Archaeology in this volume), the determination of the trace element pattern in metal objects was the first approach to the problem, understanding that this analysis could collaborate in identifying the nature of the ore (due to its similar pattern) and, therefore, its probable geographical origin. However, the abundance of those elements can be modified in the process from ore to object, through roasting, smelting, melting, alloying, etc. (Pernicka 2014). For example, it has been tested that some trace elements concentrate in the slag (and not in the metal) and that these concentrations vary according to temperature and redox conditions of the metallurgical process (Pollard and Bray 2014). Isotope analysis is another method to link metal artifacts with the metallic ores where they were extracted. Lead isotope studies are the most common, and it has been applied to lead, silver, copper, and copper-based alloys. The lead isotope ratios of a metal object reflect the geological sources of the lead, as isotopic compositions remain unchanged during the metallurgical process (Pernicka 2014). Lead isotope ratios of geological sources vary according to the age and geological history of each source, so given the lead isotope composition of a metallic object and the availability of lead isotopic data for geologic sources, researchers can match artifact with a metal ore source (Macfarlane and Lechtman 2016). One of the main problems faced by provenance studies (both lead isotope analysis and trace elements) is that recycling and mixing of metal objects would potentially erase the information from the provenance of each component. However, it has been discussed whether it is realistic to expect that in a certain region and period of time, the pool of metal available for mixing would come from different ore sources (Pernicka 2014).

Challenges for the Future and Final Words

As we intend to show in this entry, archaeometallurgy deals with a wide range of materialities and analytical methods, in order to have a more complete understanding of mineral extraction and metal production, use and distribution within a particular society in a specific period of time.

Interdisciplinary approaches are required to be able to combine the analysis of different types of data and evidences. Although current analytical methods are less invasive than in the past, most of the nondestructive techniques require smaller or polished samples for obtaining accurate results. Moreover, objects have to be moved from museums or research institutes to the laboratories where the necessary equipment is located. Portable devices are really useful in cases where transport is not possible, but many questions remain unanswered due to their limits of detection. Curatorial constraints toward conservation of the pieces are understandable as the archaeological record needs to be preserved for future generations. There is, however, some evidence that is more frequent and has little aesthetic value as slag or technical ceramics. In this case, as Martinón-Torres and Rehren (2014: 130) state, invasive analysis generates "a plethora of information not otherwise obtainable. This is not a destructive analysis – it is a constructive analysis of the first order". Another challenge archaeometallurgists face, as any other archaeologist or material scientist, is budget. The choice of analytical methods should be guided by the research question and aim, but in reality, the selection is mainly determined by the cost of the analysis and ease of access (Rehren and Pernicka 2008).

As noted by Thornton and Roberts (2014), the study of metallurgy at the present day is not focused, as in the past, on finding metallurgical origins but in analyzing technological transfer and circulation and its mechanisms, as well as the articulation of this technology with other technologies and the social context in which they are developed. The role-play of metal production in social complexity and elite dominance is also being discussed in each case and not pre-assumed as it was before.

Another challenge for archaeometallurgists has always been creating a real interdisciplinary team where geologists, geochemists, material scientists, and archaeologists can work together, sharing research questions and combining methods and perspectives. Last but not least, as in any other research field in archaeology, archaeometallurgists need to make their studies available to local populations, sharing knowledge and research questions and developing together new ethnoarchaeological and experimental studies on mining and metallurgical practices.

Metals: Preservation and Conservation

Ian D MacLeod
Western Australian Maritime Museum, Fremantle, WA, Australia

Introduction

The challenge of providing a summary of the most relevant literature that relates to metal conservation is based on exclusion rather than inclusion. Presently there is a resurgence of energy and vigor being found in this area of applied research. The largest collection of peer-reviewed papers comes from two triennial conferences of the International Council of Museums Committee for Conservation (ICOM-CC) and a meeting of the ICOM-CC Metals Working Group. The triennial conferences of ICOM-CC were held in Melbourne in 2014 and in Copenhagen in 2017 (ICOM-CC 2014, 2017), while the Metals Working Group held a meeting in New Delhi in 2016 at which more than 70 papers and posters were published (Metal 2016). Other principal sources included the publications of the International Institute for Conservation of Historic and Artistic Works (IIC) which publishes *Studies in Conservation* as well as the *Bulletin of the Australian Institute for the Conservation of Cultural Materials* (AICCM) and that of the *Journal of the American Institute for Conservation*. Summaries of the original papers are generally referred to by the year of the conference publication, while citations from journals are reported in standard formats. The original articles can be found by using Google Scholar. Many of the papers report on the results of practical conservation assessments, analyses, and treatments that relate to the typical problems faced by those caring for our metallic cultural heritage (Figs. 1, 2, 3, 4, 5, 6, and 7).

Key Issues

Conservation of Iron

A key paper in the quest for new understanding on the nature of the interaction of iron with wood, bone, and other elements was recently reported (ICOM-CC 2014). The study of the binding between traditional Indian swords and their hilts discovered it was the traditional use of a paste made from boiled lac beetles and river sand that formed a very stable connection between the iron sword blade and the handle. The key element in

Metals: Preservation and Conservation, Fig. 3 Brass nail from the wreck of the *Rapid* (1811) with intergranular corrosion, width 1.13 mm

Metals: Preservation and Conservation, Fig. 4 In-situ corrosion measurements on the *Gosei Maru* (1944)

this work was the thoroughness of their study of traditional craftspeople throughout the subcontinent and then checking the oral histories against contemporary experimental practice. Conservation of grave goods containing a mixed collection of ferrous and nonferrous materials from the second to fourth century in Lithuania was well managed, and practical management advice is provided by the authors to assist archaeological conservators (Metal 2016).

The first definitive study on the subcritical treatment of French archaeological iron objects recovered from land-based and marine sites from the first century CE was reported at the Metal 2016 conference in New Delhi. The corrosion products were characterized with X-ray

diffraction and laser Raman, which confirmed the reactive nature of the iron (III) minerals within the matrixes. After equilibration for more than 30 h in the subcritical microenvironment, the troublesome phases had been converted into stable Fe_3O_4. The effectiveness of the methodology of sectioning the samples and providing a thorough physical examination of the materials is enough to convince the most doubting archaeologist that this "new method" has found a permanent home in the conservation repertoire (Metal 2016).

A significant breakthrough in both first aid and long-term management of archaeological iron and bronze objects takes the form of storage/treatment in Escal bags with the Mitsubishi oxygen scavenging RPS system. The work is based on a very testing environment in the collection stores of −8° to +38 °C over an annual cycle in Central

Anatolia, Turkey. The site has been worked for more than 25 years, and it dates to the early Bronze Age. The balance of the right amount of RPS material and desiccants is reviewed, and tests also confirmed that clips sealing the bags were as effective as heat sealing which increases the collection management flexibility. The combined system gave protection during excavation periods (up to 1 week) and during the break between annual excavation programs (Metal 2016).

Phosphoric iron has been misunderstood by conservators and archaeologists alike, but recent experimental archaeology has shown that despite the major impact of phosphorus impurities on microstructure of the cast iron alloys, they could be effectively worked and treated to make steel for swords. This new approach may stimulate a review of the finds of archaeological iron and lead to provenance studies of the ore bodies (Metal 2016).

Aerobic Corrosion Products and Decay Mechanisms

Scott and Eggert summarize patination of cast iron and steels in a compelling chapter in their book. Not unexpectedly, many of the combinations of chemicals used in the patination of iron objects are closely related to the reagents that are currently used to etch iron alloys and reveal, through differential oxidation rates, the phases that determine the properties of the alloys. The characterization of the physical, structural, and color properties of goethite, lepidocrocite, akaganéite β-FeOOH and schwertmannite $Fe_{16}O_{16}(OH)_y(SO_4)_z.nH_2O$, feroxyhyte δ-FeOOH, ferrihydrite $Fe_5O_6(OH)_3.3H_2O$, bernalite $Fe(OH)_3.nH_2O$, and hematite α-Fe_2O_3 are expertly summarized.

A major advance in understanding the distribution of iron chlorides in historical Roman nails has been developed through an X-ray tomography study which was combined with neutron diffraction work. Measurements were done before and after traditional treatment with alkaline sulfite solutions. One of the real challenges of dealing with significant archaeological iron objects is the inability to determine how effective a treatment has been without resorting to significant intervention, such as drilling samples for wet chemical analysis. This new approach shows great promise and will be a useful additional method that can be applied to significant cultural objects to ensure the effectiveness of treatment programs (ICOM-CC 2017).

Treatment of Iron-Organic Composites

Desalination of composite organic and iron archaeological artifacts still presents real challenges for material conservation. This is due to the fundamental incompatibility of chloride-infested iron, which wants a highly alkaline environment for stability, and the desire of organic materials to be in a near-neutral condition. Collaborative research in Switzerland and the USA showed that coatings of dodecane go a long way to protecting the organic remains during the prolonged immersion periods in alkaline solutions that are needed to stabilize the iron components (ICOM-CC 2017).

The role and significance of iron sulfides in the fate of formerly waterlogged wooden vessels such as the *Wasa* (1628) and the *Batavia* (1629) continue to expand, with most of the effort going into the characterization of the minerals. It is only when formation mechanisms are fully understood that there is hope that future resolution of the oxidative degradation, which follows successful stabilization of the waterlogged wood, can be effectively managed. The pyrophoric nature of the iron sulfide mackinawite explains why some freshly excavated cannon balls can corrode so rapidly that they begin to steam. A critical review of coating systems for reactive pyritic mineral specimens shows that storing them at a relative humidity below 40% is the best approach (Scott and Eggert 2009).

Treatment Options for Nonferrous Materials

The chemical stratigraphy of Renaissance bronzes revealed composite patinas consisting of primary layers reflecting dezincification and secondary layers of botryoidal copper sulfate structures using synchrotron- and neutron-aided techniques. These phases were topped with organic layers which explain the apparent mystery behind the

remarkable aesthetic beauty of the bronzes (ICOM-CC 2014). A synchrotron study of a 1697 Dutch pewter plate recovered in the nineteenth century revealed that the raw materials were English and that the complex patina of the de Vlamingh plate was due to significant amounts of copper impurities in the Cornish tin (ICOM-CC 2014).

A real headache for archaeological metal conservators is how to manage the impact of repetitive treatments on the same historical object. Collaborative research in Spain and Portugal has demonstrated, on model systems, that electrochemical reduction of silver and lead corrosion products can take place up to six times without loss of surface materials. Although limited to standard metal tokens, the news that potentiostatic reduction retains all the metal that had corroded and returns it to its metallic state is a very positive step forward in the long-term preservation of historic archaeological metal objects (ICOM-CC 2017).

A 4-year project involving the Getty Conservation Institute and French laboratories was focused on a series of extraordinarily fine second- to fourth-century silver archaeological objects. The research discovered historical evidence about the nature of the hoard which demonstrated the precise manufacturing techniques. The choice of tarnish removal was resolved by using ultrafine slurries of calcium carbonate with old organic coating residues being removed with a combination treatment of steam and alcohol. Details of the new transport and exhibition mounts are also reported which will ensure that the lessons learned regarding the Berthouville silver treasure are made available to the archaeological world at large (ICOM-CC 2017).

A major development for the proper interpretation of the milieu of corrosion products on archaeological bronzes has shown that it is the presence of human remains, providing a rich source of phosphate, that facilitates the formation of sampleite, $NaCaCu_5(PO_4)_4Cl.5H_2O$. In higher-sulfate soils, the hydroxy sulfate connellite $Cu_{19}Cl_4(SO_4)(OH)_{32}.3H_2O$ is a major copper mineral, and recent X-ray diffraction studies show that what was once believed to be paratacamite is in fact $(Cu,Zn)_2(OH)_3Cl$, i.e., a mixed copper-zinc hydroxychloride. The three isomeric forms of $Cu_2(OH)_3Cl$ are atacamite, paratacamite, and botallackite, and it has been determined that the old anarakite is now herbertsmithite $Cu_3Zn(OH)_6Cl_2$ (Scott 2017).

Detailed analysis of a late Bronze Age object by XRF and XRD showed that bronze disease is unequivocally related to the presence of nantokite (CuCl) in the subsurface pits. Scanning photoelectron microspectroscopy showed that there is selective corrosion on the Sn-rich phases with synergistic Sn and Cu attack triggered by a peculiar type of decuprification characterized by the formation of Sn(OH)Cl because of local HCl generation in the corrosion process (Bozzini et al. 2017).

Advances in Metal Conservation and Corrosion Inhibition Methodology

A breakthrough in the management of decay of archaeological bronzes involves the use of smart nanostructured coatings. The method involves separation of toxic corrosion inhibitors from the coating system. For example, benzotriazole is contained in halloysite nanocontainers in a hydroxypropyl cellulose matrix which is then applied to bronze objects. X-ray photoelectron spectroscopy was used to monitor the corrosive attack in 3 wt.% NaCl solutions. Results show that films can be efficiently used as a transparent bronze corrosion inhibitor coating. Some films exhibited a "self-healing" behavior, allowing a selective release of BTA during the corrosion process induced by chlorides, as well as a protection barrier effect due to the organic matrix (Metal 2016).

A very useful addition to the suite of tools for conservation of archaeological metals has been provided through a study of the variation of the voltage (corrosion potential) of metal objects sitting in treatment or storage solutions. Increasingly positive voltages show that the patina is interacting with the cleaning solutions to create a passive film that lowers corrosion rates. When the voltages become increasingly negative, it means

that the cuprite patina is being dissolved. This monitoring process allows an archaeologist conducting field stabilization to monitor the progress of a treatment or to know when to stop immersion in a treatment bath (Metal 2016). Conservators of composite archaeological items have been happy to engage with a new device, *the Pleco*, which is a free-sourced localized electrolysis piece of equipment that can be brought to objects in the collection and exhibition areas and the restoration work conducted in situ (Metal 2016).

An alternative to the hydrochloric acid-thiourea-based silver dip for removing tarnish from archaeological metals involves using sulfuric instead of hydrochloric acid with the critically important inclusion of xanthin gum. The gum appears to minimize the loss of finely attached precious metals since there was no mechanical buffing involved (Metal 2016).

Preventive Conservation

X-Ray Fluorescence Analysis of Metals

A guide as to how to optimize the reliability of portable XRF analysis of archaeological metals was developed through analyses of alloy coupons before and after artificially aging them. It is critically important to optimize the distance from the source to the artifact surface as many "weak" X-rays, such as tin, are attenuated by the air (ICOM-CC 2014). An exciting breakthrough for restorers of gilded artifacts involves the incorporation of small amounts of indium and palladium into gold leaf. The additive elements do not alter the properties of gold leaf but instantly allow discrimination of "new" and "old" gold through routine measurements using X-ray fluorescence (Metal 2016).

Responses to Traditional and Modern Coating Systems

The Getty Conservation Institute applied full forensic skills to the deconstruction of commercial *Incralac* and developed laboratory versions of the traditional commercial coating. This work was promoted by the increasingly severe regulations regarding emissions of volatile organic compounds and import restrictions. For archaeological conservators facing such challenges, the work provides new hope for both field and laboratory conservation of copper alloys (ICOM-CC 2017).

Prohibitive costs and customs regulations on imported conservation chemicals mean that important archaeological conservation can be extremely challenging; this is where the use of natural chemicals from fruit extracts provides ways of overcoming these issues. Indian conservators found that extracts from crushed fruit of the plant *Emblica officinalis* reacted with all the chloride-containing iron corrosion products associated with problematic archaeological iron objects. The extract converted reactive minerals into stable magnetite (Fe_3O_4) and left surfaces with a pleasing dark lustrous patina. If a matte finish is required, the treated objects can be coated with an appropriate matting agent (Metal 2016).

Conservation of Large Objects

Although not formally archaeological, the treatment of the massive Column of the Grande Armée, or "Vendôme Column," is pertinent to very large metal objects from a buried context. The 260-m-high frieze comprises 425 bas-relief panels cast from the bronze cannon captured during the Napoleonic campaign of 1805. The column was rebuilt in 1875 with no treatment for 130 years. The elemental composition of the different patinas was determined by X-ray fluorescence spectroscopy, X-ray diffraction, and cross-sectional metallography. The large variations in the lead and tin content brought about a dynamic visual range of colors on the patina that varied from greenish-white via blue-green to black. The metal was mechanically cleaned using urea formaldehyde powdered resin with some corundum media. Re-patination with a copper nitrate solution was necessary to restore the color of the patina (Metal 2016).

Experimental Archaeology

Characterization of four bronze shields dating to c.1300–800 BC from the British Museum collection and one experimental replica showed them to

have 9–14% tin in the bronzes with trace impurities. Cold working of some of the shields brought up to a 60% reduction in the as-cast thickness. The high microhardness values of the original shields and the survival of the replica shield in a combat test suggest that the Bronze Age shields could have been used in combat rather than being merely ceremonial. This data provides the opportunity for reinterpretation of historical archaeological analyses (Metal 2016).

Air Borne Pollution

In the last few years, the impact of particulate pollution on the corrosion of metals in heritage locations has diminished simply because of improvements in collection management of museum metallic objects. The impact of dust on metallic corrosion and how important the orientation of the surfaces can be, particularly inside a showcase, has been the subject of a recent expert research project (ICOM-CC 2014). Special care and attention to the early seventeenth-century ebony- and silver-decorated Walbaum Cabinet at the Kunstgewerbemuseum (Museum of Decorative Arts) in Berlin demonstrates the extraordinary care needed for rare and precious objects. To prevent the re-tarnishing by acetic acid off-gassing from the timber on more than 3400 individually cleaned and reassembled silver parts, the object was stabilized through the introduction of a custom-made air filtration system that prevents buildup of vapors (ICOM-CC 2014). Chinese workers from heavily polluted cities found that high levels of ozone in moderately humid conditions have a significant impact on the corrosion behavior of bronzes in museums. A surprising discovery is that bagging objects has turned out to be beneficial since bagged objects demonstrated greater RH stability than theory would suggest. It appears that, in storage, without temperature or humidity control, the benefits of bagging objects to reduce the risk of pollution and insects and to buffer against short-term fluctuations in RH may outweigh the risk of mold growth within the bag (ICOM-CC 2014).

Introduction

Historical archaeology is a relatively new research field in Mexico. In the past, it was overshadowed by the archaeology of pre-Hispanic cultures, which served the State purpose of constructing a unified national identity. Today, the archaeology of the recent past is a well-recognized research strategy and considered necessary for the protection and investigation of the material remains dating to the Colonial and Republican periods. Initially, the archaeology of these periods was related to restoration projects and to rescue archaeology in urban centers. Over the years, however, the number of research projects with scientifically informed questions in both urban and rural areas has expanded, focusing on regional studies, settlement patterns, excavations at religious and secular sites, and the exploration of themes related to colonialism, identity, and consumerism, among others. Even though academic interest in the archaeological study of historical periods has increased over the past decade, there is much to be done as new research questions and topics arise which aim to contribute to a more complete narrative of Mexico's multicultural past and identity (Fig. 1).

Definition

The term historical archaeology in the New World and specifically in Mexico traditionally refers to the study of the material remains that pertain to the periods that follow the cultural contact between European and Native populations and the impact that the colonization processes had on both groups. The subject matter of historical archaeology in Mexico comprises the archaeological remains and documentary sources of Indigenous and European origin from the Colonial period (c.1519–1521 to 1820) and to the Republican era (1821 to the present) (Charlton and Fournier 2008).

Historical Background

Since its early development, archaeology in Mexico has been linked to the interests of the State. The research agenda and results derived from archaeological research have been used by the State to construct a national ideology through the National Institute of Anthropology and History (INAH) whose mission is to preserve, reproduce, and study this identity. Pre-Hispanic remains pertaining to an indigenous cultural heritage have been used by the State to reaffirm and glorify a native past, and thus, the periods predating the Spanish conquest have been traditionally considered the subject matter of archaeology. As a result, generally the limited funding destined for archaeological research has been granted mostly to projects that focus on pre-Hispanic sites, relegating the study of the postconquest era to local ethnohistorians and historians. This contrasts sharply with projects conducted by American archaeologists who may be funded with larger resources for the study of the remains pertaining to the Mexican Colonial and Republican periods (e.g., Charlton and Fournier 2008; Charlton et al. 2009).

Mexico: Historical Archaeology, Fig. 1 Mexico with areas and important places mentioned in the text

However, the situation has been changing in recent times.

Historical archaeology is a relatively new research strategy in Mexico. The first approach to archaeological contexts from the colonial period dates to the 1930s, represented by studies of historic ceramics found in excavations in downtown Mexico City designed to understand technological and stylistic changes of post-conquest Aztec ceramics (e.g., Charlton and Fournier 2008). However, it was not until the early 1970s when the archaeology of historic sites acquired relevance in Mexico. This resulted from the discovery of the Aztec main temple (*Templo Mayor*) and from several public works projects in Mexico City, such as the construction of the subway, and from conservation projects in the Metropolitan cathedral and in the National Palace. The excavations in these sites uncovered material culture from historical periods that had been overlooked by archaeologists in previous decades and awoke the interest of some researchers to develop typologies of historic ceramics (e.g., Charlton et al. 2009) (Fig. 2).

Since 1972, Mexican legislation requires that archaeologists protect and conduct research of both pre-Hispanic and historic remains threatened by contemporary public works. This has promoted the interest of Mexican archaeologists to study them under a legal framework and the supervision of a government agency, the Instituto Nacional de Antropología Historia (INAH)

Mexico: Historical Archaeology, Fig. 2 Remnants of the Aztec Main Temple (*Templo Mayor*) in Mexico City

(Fournier and Charlton 2012). By the late 1970s, historical archaeology was a consolidated research strategy in Mexico, and trained archaeologists were put in charge of the excavations in buildings dating to the Colonial and Republican periods that were subject to restoration.

Through INAH's Office of Salvage Archaeology, historical archaeology has been linked to rescue and salvage excavations conducted in religious and secular buildings in Mexico City. An interesting case study is that of the convent of La Encarnación where the skeletal remains of nuns were discovered in graves (e.g., Charlton et al. 2009). Some important projects have been developed in areas outside the capital, for example, at the site of El Olimpo in the main square of Mérida, Yucatán, the city of Campeche, and in the Soconusco region in Chiapas, where a Dominican church was explored archaeologically prior to the construction of a dam (e.g., Charlton et al. 2009; Fournier and Velasquez in press). Also, the rescue excavations at the site of Santa Inés, located in the neighboring area of the Augustinian monastery of Zempoala, Hidalgo, revealed a late postclassic and early colonial indigenous town inhabited by the Otomí. The archaeological materials that were recovered at this site suggest that the life of the native inhabitants of this settlement continued after the conquest without major changes (Fournier and Charlton 2012). Moreover, the INAH Project for urban archaeology has excavated extensively the historic center of Mexico City. Even though the main purpose of this project is to uncover material remains from the Aztec occupation period, research on historic ceramics and zooarchaeological and botanical remains has also been conducted (e.g., Fournier and Velasquez in press) (Fig. 3).

Many historical archaeology projects have also developed from the need to preserve and restore monasteries, convents, hospitals, churches, and palaces in urban centers. These projects adapt the buildings to public or private use such as museums, universities, banks, government offices, or hotels and to promote tourism in Mexico City, Oaxaca, Puebla, and Cuernavaca, in the State of Morelos (e.g., Charlton et al. 2009; Fournier and Charlton 2012). These investigations have integrated archaeological, documentary, and ethnohistorical data in the study of

Mexico: Historical Archaeology, Fig. 3 Santa Inés site, Hidalgo. Excavation of early colonial houses and patios

material remains from the sixteenth to the twentieth centuries (Charlton and Fournier 2008). A good example of how archaeological research was conducted parallel to the agenda established by architectural restoration can be observed in the convent of San Jerónimo in Mexico City (e.g., Charlton et al. 2009). Here, the main objective of the project was the restoration of the architectural complex, but also archaeological remains were excavated and ceramics, glass, and human remains analyzed. Another example of how this research strategy was parallel to restoration projects is the monastery of Santo Domingo de Guzmán in Oaxaca (Fernández Dávila and Gómez Serafín 1998) (Fig. 4).

Mexico: Historical Archaeology, Fig. 4 Glazed earthenware bathtub excavated at one of the cells of the convent of San Jerónimo, Mexico City

Key Issues/Current Debates

Regional Studies

The most relevant regional studies of historical archaeology are those by Thomas H. Charlton in the Otumba area in the Basin of Mexico. They include intensive surface surveys, surface collections, and excavations along with ethnohistorical studies of the region. The project aimed at reconstructing aspects related to the cultural

Mexico: Historical Archaeology, Fig. 5 Ruins of a nineteenth century ranch in the Mezquital Valley, Hidalgo

contact between Indigenous and European populations, acculturation processes, demographic collapse, ecological change, and the development of rural settlements (e.g., Charlton et al. 2005). Another important regional study attempted to reconstruct the changes in settlement patterns, ceramic diversity, and consumption from the postconquest period to the twentieth century in the northwest of the States of Puebla and Tlaxcala and in southern Hidalgo (e.g., Fournier and Charlton 2012). Also in the Basin of Mexico in the case of rural Xaltocan, the work by Rodríguez-Alegría (2010) contributed to the understanding of how indigenous groups utilized Hispanic ceramics as symbols of social status. His research has enabled the comprehension of changes in labor patterns and demography by examining the production of obsidian tools during the postconquest period (Rodríguez-Alegría 2008).

In the Mezquital Valley, Hidalgo, research projects with an interdisciplinary approach, addressed the construction of Otomí indigenous identities and the emergence of resistance strategies to the Spanish conquest. These investigations considered the agave exploitation and the consequences of the introduction of ideological and economic systems, marked by Otomí family chapels and rural settlements, as well as the development of privately owned rural residential estates associated with animal husbandry and agricultural activities (*haciendas*) and ranches resulting in landscape transformations and the marginality of the indigenous population in this region (e.g., Mondragón et al. 1997; Fournier and Mondragón 2003) (Fig. 5).

Other examples of regional studies integrating surface surveys, excavations, and documentary evidence were conducted in the Isthmus of Tehuantepec, Oaxaca (Zeitlin 2005), the Soconusco region, Chiapas (Gasco 2005), and the Maya region (Alexander 2012). These investigations examined changes in social inequality, land tenure, landscape, settlement patterns, and ecology to address the transformations that occurred in indigenous communities during the colonial period. In the case of western Mexico, regional projects in the Pátzcuaro Basin, Michoacán, have approached the political, economic, and ecological impact of colonial rule and the conflict between Tarascan indigenous groups and Spanish settlers (Pollard 2005). In the port of San Blas, on the coast of Nayarit, a major trading post connecting the Pacific Coast of New Spain with the California missions, surface surveys have provided information on the daily lives of the inhabitants of this bay and aspects related to the trans-Pacific trade networks between Mexico and Asia (e.g., Fournier and Charlton 2012).

The study of Jesuit missions, particularly the Jesuit College of San Felipe and Santiago in Sinaloa de Leyva and towns in the neighboring region

Mexico: Historical Archaeology, Fig. 6 Excavations at the Jesuit church of Sinaloa de Leyva

of El Fuerte, Sinaloa, has contributed significantly to the archaeology of northwestern Mexico (e.g., Fournier and Charlton 2012). These research projects have provided information on the changes from pre-Columbian to historic indigenous and Hispanic ceramic traditions, and on the changes in subsistence strategies and settlement patterns during the colonial and Republican periods (Fig. 6).

Rural Settlements. Ranches and Haciendas

Studies with a regional scope and that have focused their interest on rural settlements like ranches and *haciendas* are part of a growing field in the archaeology of Mexico. Several projects have been developed in the Mezquital Valley, State of Hidalgo (Fournier and Mondragón 2003); in the *hacienda* of San Miguel Acocotla, Puebla (Newman 2010); and in the *hacienda* de Pánuco, Zacatecas, founded for smelting and refining silver (Fournier and Blackman 2010). The research undertaken in these areas relate to the construction of ethnic identities, the economic activities, and the life of workers, administrators, and owners at the *haciendas* (Fig. 7).

Other projects have concentrated in Yucatán. These investigations aim to understand the social and economic changes that occurred during the past 500 years related to settlement patterns, towns, and the exploitation of natural resources. The investigations combined documentary sources with settlement patterns and household archaeology. Major contributions to the archaeology of this region addressed the changes in the economic and political landscape during the Caste War (1847–1901) and the correspondence regarding place, identity, agrarian practice, and landscape since the Spanish conquest (Alexander 2012). Furthermore, in Hacienda Tabi, Sweitz (2012) examined the lives of the workers and explored the built environment to address power relations and changes in social status, production, and the organization of labor in the context of capitalism.

Colonialism, Production, and Consumerism

Studies that have dealt with the impact of Spanish colonialism have addressed changes in the production and consumption of material culture, namely, ceramics and other products like salt. These investigations have focused their attention on the changes in indigenous technologies, the introduction of European techniques, and the use given to local and imported ceramics by colonial society.

Artifacts such as Aztec tradition ceramic figurines from the Basin of Mexico have been studied, illustrating changes and continuities in styles and techniques as well as the appearance of European dress and facial features substituting pre-Columbian deities in the case of anthropomorphic figurines (Charlton et al. 2005). Research on the impact of colonialism on indigenous ceramic production and consumption is well exemplified by studies that have considered the red wares from Cuauhtitlán. The results of these studies suggest that ceramic traditions from the late postclassic period suffered only minor changes during Spanish rule and that this ware was popular among members of the Hispanic elite who used it for lavish display (e.g., Charlton and Fournier

Mexico: Historical Archaeology, Fig. 7 Ruins of the hacienda de Pánuco, Zacatecas

2011). Furthermore, the patterns of consumption of this ware have enabled the exploration of the relationship between these ceramic objects and the construction of power, social status, and ethnic identities. The changes that were introduced by the Spanish colonizers to indigenous ceramic technologies, vessel forms, and decorative styles in central Mexico have also been the subject of an extensive study by Hernández (2012). Other examples of this approach include studies of indigenous plain or painted wares from Oaxaca (Zeitlin 2005) and brown wares from northern Mexico (Brown et al. 2004) (Figs. 8 and 9).

The application of archaeometric techniques through neutron activation analysis of glazed wares has provided rich insights into the relationships between production, distribution, consumption, and technological change of Spanish colonial wares. Another important ongoing research deals with the identification of production centers of majolica, its commercialization in the Viceroyalty of New Spain, and aspects related to consumerism and the construction of identities. Potters in New Spain adapted European ceramic technologies to the new environment in order to manufacture objects in a style that emulated Spanish majolica and by the 1600s Chinese porcelain in order to satisfy local consumers (e.g., Fournier et al. 2009). The identification of production centers in Spain and Mexico have enabled the construction of the geographical distribution of majolica and aspects related to commercialization and consumption, indicating that the value attached to majolica by colonial elites as a symbol of social status and identity impacted the production of this ware (Fig. 10).

Mexico: Historical Archaeology, Fig. 8 Early colonial ceramic figurines from Mexico City

In addition to these studies, the work by Gasco (1992) explored cultural continuity in Ocelocalco, Chiapas. At this site, indigenous communities were active participants in the colonial economic system through the cacao trade. The control exercised by these groups over cacao production enabled them to consume large quantities of majolica and Chinese porcelain. Gasco's work has contested traditional views that have established a straightforward relationship between ethnic identity and material culture of a Hispanic tradition. Also, within the field of colonialism and consumerism, Palka (2005) examined the responses of Lacandón Maya in Chiapas to colonialism during the nineteenth century that resulted in culture change, transformations in settlement patterns, and consumption of local and imported material culture. Finally, Kepecs (2005) explores aspects related to the commercialization and consumption of salt, for example, and the impact of European incipient capitalism on Maya economy in the Peninsula of Yucatán.

Mexico: Historical Archaeology, Fig. 9 Early colonial redware tripod plate depicting an Aztec Warrior, found in excavations in Mexico City

Missions, Presidios, Reales, and Roads

Historical archaeology at missions (European religious foundations in indigenous settlements), *presidios* (forts that housed soldiers who protected the inhabitants from Indigenous assails), *reales* (mining centers), and roads is mainly concentrated in northern Mexico, including Chihuahua, Baja California, Sinaloa, Sonora, and Zacatecas. The research conducted at mission sites offers a valuable opportunity to explore the religious, economic, and social transformations in the lives of indigenous populations as a result of the Spanish conquest. Acculturation processes, the degree of interaction between native and Hispanic communities, the transformations in social organization, settlement patterns, subsistence and the introduction of agricultural practices, and the development of ceramic traditions are some of the major research topics conducted at mission sites (e.g., Brown et al. 2004; Fournier and Charlton 2012; Fournier and Velasquez in press).

Mexico: Historical Archaeology, Fig. 10 Seventeenth-century Kraak porcelain dish and Puebla Blue-on-White majolica dish emulating Chinese patterns

The missions and the *presidios* were connected with other regions of New Spain and with the *reales* in the north through major roads, like the Royal Road or *Camino Real de Tierra Adentro* and its branches, over which the silver extracted from the mines in the north was transported to Mexico City and the merchandises made in the Viceroyalty or imported from Europe and Asia were distributed, supplying avid consumers all over Mexico. The archaeological research at these sites has contributed significantly to the reconstruction of changes in the production and commercialization of products throughout the colonial period (e.g., Brown et al. 2004; Fournier and Velasquez in press).

The African Diaspora

There are few projects dedicated to the study of the African descendants in Mexico. This is due in part to the difficulty encountered in the identification of the material culture of groups with African ancestry in the archaeological record because of the interracial and cross-cultural processes among African, Indigenous, and Hispanic groups throughout the colonial period. Despite this, Fournier and Charlton (2008) have addressed how slaves and their offspring who served Spanish women, for example, were richly attired for public display and stood as symbols of social status in urban settings. Other investigations have focused on the analysis of the remains of Africans and mulattos contributing to the understanding of their lifestyles (e.g., Gallaga Murrieta 2009).

International Perspectives

Historical archaeology projects in Mexico have been confined largely to the study of sites located within the geographical boundaries of the country, although there have been exceptions to this, where Mexican and American archaeologists have collaborated to expand investigations into the United States. Researchers in Mexico seldom expand their area of interest to regions that were at one time under the political control or responsibility of New Spain, for example, Guatemala and Florida, respectively, and that were part of a complex network that connected individuals and products. These regions have an enormous potential for exploration of processes like the establishment of religious and secular institutions, commercial relationships, conflict, navigation, regionalism, and the construction of ethnic identities, among others.

Since the 1970s, processualist, materialist, structuralist, and, to a lesser extent, postmodernist frameworks, derived from American, English, and French traditions, have permeated the theoretical development of archaeology in Mexico. However, while these approaches are familiar to most archaeologists in the country, they are seldom applied to specific research questions or to the interpretation of the results. Moreover, as opposed to the United States and Europe where there are important theoretical contributions, in Mexico, there is an urgent need to protect the cultural heritage and to develop more theoretical and methodological chemes. A critical situation that has affected the dissemination of methodological developments and the results derived from research projects conducted by Mexican students and professional archaeologists is that their work is seldom published in languages other than Spanish, or presented at international symposia, and thus their international impact is limited.

Future Directions

In the future, historical archaeology in Mexico should develop investigations with specific research questions with an emphasis on studies with a regional scope in rural areas as most projects have concentrated in urban centers, mostly in Mexico City. The design of projects with specific research questions should provide better results that are often not attainable through salvage and rescue excavations, as the results of these are often limited to the production of descriptive field reports. The archaeological materials recovered at these excavations are processed but seldom subject to further analysis and interpretation. This is a crucial task for the development of the

discipline, since it is a fertile setting where contemporary theoretical and methodological approaches can be applied.

INAH's need to protect the cultural heritage and construct a common past, largely based on pre-Hispanic cultures, has relegated the study of the Colonial and Republican periods to historians and ethnohistorians. This constitutes a major hindrance for students and scholars who are interested in conducting archaeological research of the postconquest and modern periods. Therefore, it is necessary to emphasize the potential that this research strategy has for the study of the recent past. This could be attained through the dissemination of the results through a wider variety of local journals and finding new forums in which to present them to the public. While there are some optional modules on historical archaeology offered at the National School of Anthropology and History in Mexico City and at the University of the Americas, in Puebla, it is necessary to create compulsory theoretical and practical modules as part of undergraduate programs to train students in this research area.

Interdisciplinary approaches have been traditionally employed in the historical archaeology of Mexico, by integrating archaeological, ethnohistorical, historical, ethnographic, and zooarchaeological studies. Human osteology and bioarchaeology are usually applied to the analysis of human remains pertaining to historic periods to explore health conditions, life expectancy, nutritional aspects, and the effects of toxic agents on the populations under study (e.g., Fournier and Charlton 2012). However, these studies are usually conducted by physical anthropologists and done independent of archaeological studies and thus their scope is limited to understanding the social context. In recent years, the application of GIS and geophysical techniques have been applied often in rescue and salvage excavations and in the restoration of buildings. However, the main objective has been to recover as much data as possible without further archaeological interpretation of the results, thus limiting the potential that these techniques have. In the future, it will be necessary to apply them to well-defined research questions.

There are few investigations that have been conducted at industrial sites. To date, they include a paper mill in Mexico City, leather tanneries and bottled soda factories in Puebla (e.g., Fournier and Charlton 2012), surveys, excavations, and PIXE analyses of artifacts at the mining district of Real del Monte close to Pachuca, Hidalgo (e.g., Oviedo Gámez et al. 2010). This research has aimed at reconstructing the productive processes and studying in detail the artifacts associated with the end products. However, it is necessary to conduct more studies in this field that focus on aspects related to the life of workers and artisans as these provide insights into an important component of the past of Mexico that is seldom the subject of research projects.

As historical archaeology expands in Mexico and stands as a recognized research strategy, more Mexican students and scholars can become aware of the need to conduct archaeological research on the Colonial and Republican periods and can begin to realize that the study of the recent past is as important as that concerned with pre-Hispanic cultures. If this is acknowledged, then historical archaeology research projects could be incorporated into the institutional agenda. This would enable the reassessment of the national discourse that aims to construct a unified identity, based on the ancient indigenous past, and include a more culturally diverse one. Also a larger collaboration between Mexican scholars and scholars abroad should be aimed at developing projects with a wider regional scope. The potential that historical archaeology has for exploring topics that are relevant to local and international debates such as colonialism, racism, plantation archaeology, identity, gender, and conflict among others is yet to be explored.

Mexico: Underwater Archaeology

Pilar Luna Erreguerena
Subdirección de Arqueología Subacuática, Instituto Nacional de Antropología e Historia, Mexico City, Mexico

Introduction

Since its creation in February 1980, the underwater archaeology area at the Instituto Nacional de Antropología e Historia (INAH, National Institute of Anthropology and History) has undertaken assorted projects both in maritime and continental waters, with a multidisciplinary, interinstitutional, and international approach; promoted the training of archaeologists and other young specialists in disciplines related; received the support of national and international institutions and individuals; participated in national and international forums and councils, coordinating symposiums, colloquiums, and conferences within Mexico; dedicated special efforts to the dissemination through assorted means; and maintained its strong position regarding the defense of Mexico's underwater heritage.

INAH's Department of Underwater Archaeology was promoted to a Vice Directorate in 1995 and was headed by archaeologist Pilar Luna Erreguerena from February 1980 to April 2017, when Dr. Roberto E. Junco replaced her. Counting with the presence of colleagues mainly from the United States has been crucial in the development of Mexican underwater archaeology.

Definition

Mexican underwater archaeology has passed through three important stages: (1) 1980–1994, the creation of this area within INAH until the First Underwater Archaeology Diplomate took place; (2) 1995–1998, the area was promoted, and two main projects – the 1630–1631 New Spain's Feet Research Project and the Inventory

and Diagnosis of Submerged Cultural Resources in the Gulf of Mexico – began. The first sensing remote control equipment was designed and assembled with the assistance of colleagues from the USA National Park Service's Submerged Cultural Resource Unit; and (3) 1999 to the present, other important investigations began, among them, one through which significant results regarding the first groups which came from Beringia to America are being obtained and Mexico's presence in international councils increased, including its role in the elaboration and ratification of UNESCO 2001 Convention on Underwater Cultural Heritage.

Historical Background

Mexico's underwater archaeological patrimony was ignored and looted during many years (Luna Erreguerena 2014a: 4864). INAH's Subdirección de Arqueología Subacuática (SAS, Vice Directorate of Underwater Archaeology) has fulfilled a permanent campaign to make people aware of the existence and value of this legacy and a struggle against major threats coming from treasure hunters to minor looting coming mainly from groups or individuals who are related to marine and continental waters, like fishermen, managers, tourism agencies, and divers.

Key Issues/Current Debates

New and advanced technologies have been applied; more renowned specialists, national and foreign, have joined to Mexican teams to collaborate in main projects; and new attempts from treasure hunters have been defeated.

Main Projects

The 1630–1631 New Spain Fleet Research Project (1995 Onward)

This continues to be an ambitious project in search of *Nuestra Señora del Juncal*, one of the two flagships of this fleet which sailed from Cadiz in 1630 and lost several ships in October 1631 in the Gulf of Mexico due to strong winds known as *nortes*. Its cargo included a considerable amount of silver coins, fact that has attracted the attention of treasure hunters groups; however, INAH's Council of Archaeology and the underwater archaeology area have stopped all attempts to get an official permit to explore and explode this shipwreck (Fig. 1).

Nine field seasons took place between 1997 and 2012. The 2012 one marked a turning point: a team of experts from Mexico and the United States participated in the works and in the training in marine geophysical techniques applied to underwater archaeology; National Autonomous University of Mexico's (UNAM) oceanographic vessel *Justo Sierra* could be used; it was the longest field season ever fulfilled (45 days); Mexican Navy support was received through special fast boats which every week transported

Mexico: Underwater Archaeology, Fig. 1 Ceremonial wood serpent/thunder-shaped objects and cactus leaves and points, already conserved, recovered from the two lagoons in the crater of the Nevado de Toluca volcano. (Photo: Ricardo Castro, courtesy and copyright of INAH/CNCPC)

specialists and equipment to where the *Justo Sierra* was and then back to the port of Progreso, Yucatan; and 1157 magnetic anomalies and sonar targets were recorded, post-processed, and classified according to their importance, selecting 83 as priorities (Luna Erreguerena 2013; Junco Sánchez and Trejo 2016).

In June 2014, a Memorandum of Understanding was signed between Spain and Mexico to work together in this project, creating an example of international cooperation between two countries which in the past played the roles of the conqueror and the conquered one. Both are signatories of the UNESCO 2001 Convention on the Protection of Underwater Cultural Heritage, having participated as well in the experts meetings for its elaboration. Plans are on its way to fulfill a join field season in 2018 in order to verify the most important anomalies recorded in 2012 and to keep on surveying the selected areas in the Gulf of Mexico.

The Manila Galleon in Baja California (2000 Onward)

This project, promoted since 1999 by maritime historian Edward Von der Porten with the support of INAH's Center in Baja California, acquires more importance due to the fact that, in spite of the role the Manila galleons played connecting New Spain with Asia through Philippines during 250 years (1565–1815), they remain a kind of mystery for researchers who do not have enough historic material to work with, especially of those galleons from the sixteenth and seventeenth centuries (Junco 2017: 1). In 2000, INAH's Vice Directorate of Underwater Archaeology became co-director of this investigation.

Among the main recoveries in a beach in Guerrero Negro is the collection of more than 1500 fragments of Chinese porcelain, one of the most important ones in the world. Studies on this type of ceramic are few, so one of the objectives is to continue the research of this site in order to reach an understanding of these galleons, whose commercial and cultural exchange – which involved Mexico, Spain, Philippines, China, Japan, and other southeast Asian countries – influenced the New Spain society in so many and significant ways that you can even trace them today (Ibid). During the past few years, work with metal detectors has yielded several pieces of metal pertaining to cargo such as coins, locks and keys, parts of furniture fittings, as well as bolts and nails from the ship (Junco 2012).

Vice Directorate of Underwater Archaeology Special Programs Project (2003 Onward)

This project was born due to the need to structure different activities that were already taking place. Five special programs were created:

1. Legal and technical protection. Due to constant reports on archaeological material findings in marine and continental waters, priority is given to send researchers in order to verify the discovery, record it, and determine the next steps.
2. Capacitation. Permanent training is given by national and foreign experts to underwater archaeologists, specialists in other related disciplines, collaborators, students, divers, and fishermen. Experts from different countries have been invited to participate in sea campaigns and to give courses and lectures. Archaeologists and undergraduate students from other Latin American countries have also benefited from these experiences. SAS members impart periodical classes at the National School of Anthropology and History in Mexico City.
3. Dissemination. 37 years of Mexican underwater archaeology have been captured in books, books' chapters, articles, papers, lectures, mass media interviews, itinerant and permanent exhibitions, documentaries, and virtual visits of sites in national and international academic and public forums. Special publications, like comics and booklets with photos and animation, aimed to children and adolescents have been given away in schools of some of the regions where projects are taking place.
4. Conservation. Archaeologists work very closely with curators at INAH's specialized areas on this field, as well as with the Autonomous University of Campeche and the Autonomous University of Yucatan. Since the creation of the underwater archaeology area, curators began showing interest in learning how to treat cultural material recovered from aquatic means.

5. National and international collaboration. Individuals and/or institutions from Mexico, the United States, Canada, Spain, the Cayman Islands, and Argentina have shared their knowledge and experience with Mexican young researchers and students.

Underwater Archaeological Project at the Nevado de Toluca (2007, 2010, 2012)

This volcano, also known as Xinantécatl, is 80 km from Mexico City and 23 km from the city of Toluca. With a height of 4680 meters above sea level (masl), it is the fourth mountain in altitude in the country. Since the Postclassic period (900–1521 AD), it was a site of pre-Hispanic offering in the Sun and the Moon lagoons formed at its crater, both with a depth of 14 m at 4200 masl (Arce Saldaña 2009: 1).

Elements recovered in three field seasons (2007, 2010, and 2012) include ceremonial wood serpent/thunder-shaped objects – some of them more than one meter – spheres and cones made of copal (a pre-Hispanic incense), cactus leaves and points used for self-penitence, and fragments of baskets and textile. The collection of 75 pieces of copal is unique due to its excellent preservation because of the low temperature of the water, which during the works was between 7 and 8 degrees Celsius (Junco 2009: 24 and 27) (Fig. 2).

This volcano continues being a sacred place where religious processions occur. A group called "New Fire of the Sixth Sun in defense of the Mother Earth" accused archaeologists from INAH of "affecting the balance of the cosmos" when extracting the pre-Hispanic material, so for the second field season researchers requested shamans of each ethnic group living around the volcano to perform a ritual asking their deities permission to do the work; at the end, another ritual took place in order to thank the deities (Luna Erreguerena 2014b: 192).

Lithic material, little knives and arrows made of green obsidian, ceramic, jade, turquoise, and serpentine stones were recovered on land. According to expert Yoko Sugiura (2009: 39), ceramic corresponds to the late Postclassical

Mexico: Underwater Archaeology, Fig. 2 Panoramic view of the underwater chamber known as Hoyo Negro, using the technique "painting with light". (Photo: Roberto Chávez Arce, courtesy and copyright of INAH/SAS)

period (1250–1521 AD). More recent material recovered includes a kind of glazed ceramic, typical from the early colonial period, and a lead bullet from a musket.

It is believed that this volcano was a sort of a pre-Hispanic astronomical observatory which was used 1500 years ago to observe the stars and natural phenomenon. There is a place called "El Mirador" from where, still today, it is possible to see the sun rising exactly between the two Heilprin peaks, on May 16 and July 27 (Montero García 2009: 73).

Underwater Archaeology Project at Hoyo Negro, Tulum, Quintana Roo (2011 Onward)

This project is currently one of the most important ones due to the amazing information it has been providing on the first groups of people coming to America from Siberia through the Bering Strait. The site, discovered in 2007 by cave divers Alejandro Álvarez, Alberto Nava, and Franco Attolini while mapping the submerged Outland Cave of the Sac Actun system near Tulum, Southeastern Mexico, has been considered by specialists a "remarkable time capsule of the terminal Pleistocene climate and plant, animal, and human life of the Yucatan Peninsula" (Chatters et al. 2017: 119–120). They called it "black hole," as an analogy to the exterior space phenomenon. It is a chamber located in the middle of the Mayan jungle 600 m from the nearest entrance that would have been accessible before the cave flooded, around 10,000 years ago. It is 62 m in diameter and between 38 and 55 m below modern sea level (Fig. 3), where one human skeleton and numerous animal bones, some of them corresponding to megafauna, were detected (Luna Erreguerena 2011–2012: 6).

Different methods – radiocarbon, Uranium-Thorium, and Fourier transform infrared spectroscopy (FTIR) – have been used in order to date human and animal remains in laboratories of the United States, Mexico, and Denmark. The human skeleton, the most complete of the earliest yet found in America, belongs to a female who was between 15 and 17 years of age and lived during the late Pleistocene, between 13,000 and 12,000 years BP (Chatters et al. 2014). She was named Naia by Susan Bird, a member of the cave divers group – *Proyecto Espeleológico Tulum* (PET), to honor the Naiads, nymphs of classical mythology who protected fresh waters. Naia was considered among the most important discoveries of 2014 in the world (Archaeology 2015: 14–15; Tarlach 2014: 18–19).

Renowned national and foreign experts have worked together with a group of specialized cave divers trained to do archaeological recording, including three-dimensional models created through structure-from-motion photogrammetry (SfM), with the support of experts from Hydro-Technologies and the University of California in San Diego. Scientists, based on the images,

Mexico: Underwater Archaeology, Fig. 3 Part of Naia's skeleton being prepared for a tomography at the General Hospital of Specialties in the city of Campeche. (Photo: Félix Camacho Z., courtesy and copyright of INAH/SAS)

measurements done in situ, and a small number of samples, began identifying the specimens and making analyses and studies. The decision to extract some of these remains was taken after non-authorized divers altered and damaged the site and its context (Luna Erreguerena 2014c: 5).

Naia's skeleton was recovered in three field seasons, one in 2014 and two in 2016. It received conservation treatments in the Restoration Section at INAH's Center in the city of Campeche and then was brought to the National Museum of Anthropology's security vault in Mexico City. Studies by INAH together with DirectAMS (Washington), the Autonomous University of Yucatan, and the National Autonomous University of Mexico are underway, including bio-archaeological, dental anthropological, stable isotopic, radiographic, tomographic, and aDNA analyses (Fig. 4). Ancient DNA analyses confirmed Naia's Beringian origin, linking Paleoamericans and modern Native Americans (Chatters et al. 2017). Naia's estimated height is 152.6 ± 3.8 cm and her estimated potential weight, 50.36 kilos. She was, however, undernourished, had growth anomalies, and had already given birth at least once (Chatters et al. 2016).

Mexico: Underwater Archaeology, Fig. 4 Dr. James C. Chatters taking a photo of the new genus and species giant sloth found in Hoyo Negro. (Photo: Pilar Luna E., courtesy and copyright INAH/SAS)

Animal remains recorded on the floor and walls of Hoyo Negro, so far, belong to at least 27 individuals of which 11 species have been identified, five of them extinct: gomphothere (*Cuvieronius* cf. *tropicus*), sabertooth (*Smilodon* cf. *fatalis*), bear (*Arctotherium-Tremarctinae*), Shasta ground sloth (*Nothrotheriops shastensis*), and a ground sloth which resulted a new genus and species of late Pleistocene *Megalonychid—Nohochichak xibalbahkah* (McDonald et al. 2017: 1) (Fig. 5). The meaning of this Mayan name chosen by some of the researchers is "big claws dwelling in the underworld."(Note from author.) There is also an unidentified type of extinct South American canid. Extant specimens include puma, peccary, and white-nosed coati, as well as what appear to be bobcat and Baird's tapir (Chatters et al. 2014: 752). Numerous skeletons of catfish and bats are also present (Chatters et al. 2017: 122).

Other lines of investigation include geochemistry, paleohydrology, paleoclimatology, paleobotany, and micropaleontology.

Maritime Archaeology in the Port of Acapulco (2016 Onward)

In 2015, INAH's Vice Directorate of Underwater Archaeology received a report regarding the finding of archaeological material in a garbage pile next to the San Diego Fort's Historical Museum in Acapulco, in the state of Guerrero. This discovery derived in a project aimed mainly to reconstruct the history of that port activities from the sixteenth to the twentieth centuries and their effect on the local population. Archaeologists work on land and underwater, searching for evidence of such maritime activities. It is expected that this project will contribute to the Manila Galleon research from an archaeological perspective (Junco 2017: 1–2).

Land and Underwater Survey at the Media Luna Spring, San Luis Potosí, Central Mexico (1981–1982, 2016 Onward)

This was the first underwater archaeology project in continental waters back in the 1980s. In 2016, researchers revisited this pre-Hispanic offering place to make a land survey around the spring, a

Mexico: Underwater Archaeology, Fig. 5 Shipwreck from a nineteenth century steam ship recorded in the Alacranes Reef National Park in the Gulf of Mexico. (Photo: Helena Barba M., courtesy and copyright INAH/ SASAU3)

drone photogrammetry survey of the spring itself, and the area nearby in order to create a photomosaic and a 3D model. Information from local people led to the finding of a human skeleton completely submerged. Researchers obtained permission to have access to several private collections of artifacts extracted from this spring, recording around 400 pieces of ceramic and lithic, complete and fragmented (Postclassic period, 600–900 AD), which have been incorporated to INAH's national catalogue. In 2017, an underwater survey took place, identifying more archaeological deposits – human remains belonging to adults and children, ceramic figurines, and extinct fauna. The abovementioned skeleton was recorded in situ; another skeleton that had been recovered by the community and is exhibited in the Media Luna Natural Park Museum was also recorded and is currently under study (Hernández Bautista, I., email communication, September 6, 2017).

Inventories

Inventory and diagnosis of submerged cultural resources in the Gulf of Mexico (1997 onward). This is a parallel project to the 1630–1631 New Spain Fleet research. It began due to the fact that, while looking for the Juncal, 34 sites were located in the searching area of the Sound of Campeche, selected after an intense archival consultation in Mexico, Spain, and Cuba. Also in the Gulf of Mexico, other 174 sites have been located through other projects. Sites range between the sixteenth and the twentieth centuries (Barba Meinecke 2017).

Underwater archaeological atlas to record, study, and preserve cenotes in the Yucatan Peninsula (2000–2009), inundated and semi-inundated caves in the Yucatan Peninsula (2010), and other bodies of continental water in the Mexican Republic (2014 onward). The title of this project has changed according to new discoveries made in different aquatic bodies. As 2017, 91 sites have been located, dating from Pleistocene, pre-Hispanic (around 600 AD), and colonial times (Barba Meinecke 2017).

Integral project for the protection, conservation, research, and dissemination of the underwater cultural heritage of the Yucatan Peninsula (2008 onward). Hundreds of sites have been located in the coastal areas as well as in rivers, lagoons, estuaries, and terrain gained to the sea in the states of Campeche, Yucatan, and Quintana Roo. The ones located in marine waters of Campeche and Yucatan are included in the Gulf of Mexico inventory; those in the Mexican Caribbean are 58 so far. Chronology goes from the sixteenth to the twentieth centuries (Barba Meinecke 2017).

Inventory and diagnosis of the submerged archaeological and historic patrimony in the Reserve of the Bank Chinchorro Biosphere,

Quintana Roo (2006 onward). Located in the south coast of Quintana Roo, this bank is "one of the most important sanctuaries of the Mexican Caribbean." Part of the Mesoamerican Reef System, it is considered the second greatest barrier of the world, after the one in Australia. 69 sites, submerged and semi-submerged, dating from the sixteenth to the twentieth centuries, have been recorded. Almost all of them are distributed along the east barrier of the bank, witness of 500 years of navigation from Central and South America bound to Cuba, the United States, and Europe (Carrillo Márquez 2010: 65–67).

All sites of these inventories have been recorded, studied, and catalogued, incorporated in different GIS per region, and integrated into INAH's Sistema Único de Registro Público de Monumentos y Zonas Arqueológicos e Históricos (Single System for the Public Recording of Archaeological and Historical Monuments and Zones).

International Perspectives

It is a fact that underwater archaeology has gained visibility and respect as a serious discipline since Dr. George F. Bass's works in Turkey during the decade of 1960. It can be said that the same has happened in the case of Mexico where 37 years of work, besides a permanent struggle to defend its underwater cultural legacy from treasure hunters, some of which were infiltrated in high power spheres, have won a special place for this country in national and international arenas.

Mexico is part of the 2001 UNESCO Convention's Scientific and Technical Advisory Body (STAB) since its creation. Article 2.10 of this Convention establishes that "Responsible non-intrusive access to observe or document in situ underwater cultural heritage shall be encouraged to create public awareness, appreciation, and protection of the heritage except where such access is incompatible with its protection and management" (http://unesdoc.unesco.org/images/0012/001260/126065e.pdf). In 2016, Mexico presented two examples of Best Practices to be evaluated by the STAB: (1) Underwater Archaeological Museum in *Fuerte de San José el Alto* (Campeche) and (2) Underwater Cultural Heritage at the Nevado de Toluca (involving local communities with their own cultural heritage at the Nevado de Toluca).

(http://www.unesco.org/new/en/culture/themes/underwater-cultural-heritage/underwater-cultural-heritage/best-practices-of-underwater-cultural-heritage/).

Both were approved in May 2017, during the sixth session of the Meeting of State Parties at UNESCO's headquarters in Paris (http://unesdoc.unesco.org/images/0024/002489/248974E.pdf).

Future Directions

Future directions enlisted in the first volume of the Global Archaeology Encyclopedia are still valid.

Regarding the 1630–1631 New Spain Fleet project, current plans to join efforts with Spain, through the Memorandum of Understanding signed in 2014, aimed to verify the main anomalies recorded in 2012 and to complete the survey of the preselected area with more possibilities of locating *Nuestra Señora del Juncal*, are expected to led to new discoveries in 2018.

Another project with a great potential is the one at Hoyo Negro, in Tulum, Quintana Roo. Future field seasons will focus on the recovery of fauna remains which, according to experts, may provide relevant information that, together with other lines of investigation, will keep on contributing to the understanding of the context of the site itself and the Yucatan Peninsula's ecosystem during the Late Pleistocene.

Mexico's Heritage and Management

Sandra L. López Varela
Facultad de Filosofía y Letras, Universidad Nacional Autónoma de México, Ciudad de México, Mexico

Introduction

Mexico's heritage is here defined to approach the advantages and disadvantages of having a national preservation model. The pages that follow, critically, examine how the need to modernize the nation has historically and politically defined Mexico's concept of heritage. Mexico's desire for economic growth is pressuring the National Institute of Anthropology and History (Instituto Nacional de Antropología e Historia [INAH]), the stewards of Mexico's heritage, to adopt a private sector-based model. In the absence of a regulated process, the participation of the private industry has become a liability, not a preservation asset that could create a fertile employment field in heritage management, with a positive impact on Mexico's GDP (gross domestic product).

Lessons of public unrest are leading to the realization that after a century of infrastructure building and promotion of urban lifeways, Mexico's urban spaces have already created a sense of place attachment among its dwellers. Mexico's citizens demand the protection of novel heritage resources by taking their plea to the streets. Therefore, social unrest is forcing a revision of the legal frameworks defining Mexico's heritage. As will be discussed here, the model to successfully achieve a higher level of heritage protection at less cost to the government and the people of Mexico is already under configuration, amid national and international pressures.

Mexico's Definition of Heritage

Mexico defines her heritage as a patrimony comprised of three different types of properties (archaeological, artistic, and historic monuments). The National Institute of Anthropology and History is the steward of these properties, linked to the nation's history. The *Ley Federal sobre Monumentos y Zonas Arqueológicos, Artísticos e Históricos*, its regulatory framework, also known as 'Ley de 72', and still valid today, defines archaeological monuments, as the natural and built environment of those present before the arrival of the Spaniards in the 16th, including their created objects, and their human remains. Historic monuments include written documents and scientific collections, as well as, religious, military, and state architecture built between the sixteenth and nineteenth centuries. Beyond the twentieth century, heritage is defined in terms of immovable and movable modern properties, exhibiting relevant aesthetic values. The preservation process establishes the priority to protect archaeological properties over artistic and historic monuments.

Given the inalienable nature of Mexico's archaeological properties, their transfer of ownership or trading is prohibited, and sanctioned by Law. Historical and artistic properties may remain in private custody, with the ensuing responsibility to be preserved, always, under the supervision and permission of the institution. When the proprietor fails to preserve its property, INAH will carry out its preservation, and the costs absorbed by Mexico's Treasury Department. INAH is the trusted appointee to oversee the management and preservation of Mexico's heritage resources and absorbs the full costs of preservation through an assigned federal budget.

Historical Background

Mexico's definition of heritage is the result of a wide spread phenomenon in the nineteenth century of considering history as a crucial element with which to construct nations and national identity (Berger 2007). Creating national historical consciousness through monuments was very much within the spirit of the French Revolution.

In order to create such consciousness, Mexico debated which characteristics defined her national identity, as many other colonized nations did. After Mexico's Independence in 1810, the debate was divided between the conservative voices that defended Mexico's Spanish past and the liberal expressions that refused to accept that the Spanish colonial past should be part of her national identity (Berger 2007: 94). A "reconciling approach," sketched in *México a través de los siglos*, a publication by Vicente Riva Palacio, as noted by Berger (2007: 95), gave equal prominence to the nation's indigenous past and Spanish legacy, giving rise to the mestizo, her new ethnicity. The new and independent nation prohibited the extraction of Mexico's monuments, as early as 1827 (Schroeder Cordero 1983: 672). The National Museum of Mexico, founded in 1825, continues to display Mexico's past and her indigenous cultures in what it is now the Museo Nacional de Antropología.

The Mexican Revolution shaped the route for Mexico to become a modern nation in the twentieth century. Mexico had to transform the miserable living conditions of the *indios*, that after centuries of oppression under the Spanish Crown, had left them in a stage of physical, intellectual, moral, and economic underdevelopment, if the nation was to become a great country like Germany, France, or Japan, said Gamio (1916: 10). Given that "the Indian possesses a civilization of his own, which, however attractive and present the higher the degree of evolution, has lagged behind contemporary civilization" (Gamio 1916: 172). To remove these "incapacities" (Caso 1958: 52), and for the indigenous populations to contribute to Mexico's economic growth and development, their incorporation to Mexico's modern society was needed. In other words, modernizing the nation required the cultural homogenization of the country (Díaz-Polanco 1997). Few discourses of nationhood have been so contradictory, as the forging of the Mexican State, considering the indigenous life ways, their beliefs, and their illiteracy in Spanish, an impediment for economic growth as obstructions to economic growth, and at the same time, as symbols of her identity.

Despite the paradox, Mexico became one of the first countries to consider the protection of its heritage, as a fundamental responsibility of the federal government by the end of the nineteenth century. In modeling Mexico after France, a desire embodied in the architecture of downtown Mexico City, President Porfirio Díaz declared archaeological monuments as national properties in 1897, issuing in 1902, a formal law to protect them (Schroeder Cordero 1983: 672). In 1914, Mexico considered the preservation of historic and artistic monuments, including the beauty of her natural landscapes, in the *Ley sobre Conservación de Monumentos Históricos, Artísticos y Bellezas Naturales* (Rodríguez Morales 2011). Legislating over Mexico's monuments and natural landscapes led to the creation of an auditing institution, the *Inspección Nacional de Monumentos Artísticos e Históricos*, overseen by the secretariat of the Beaux Arts, the *Secretaría de Instrucción Pública y Bellas Artes* (Rodríguez Morales 2011: 206). In 1934, Abelardo L. Rodriguez, interim president of Mexico, enacted the *Ley sobre protección y conservación de monumentos arqueológicos e históricos, poblaciones típicas y lugares de belleza natural*, a law protecting archaeological and historical monuments, as well as traditional communities and sites of unique natural beauty, possibly inspired by the Athens Charter. (SEP 1934), possibly inspired by the Athens Charter, that even paid attention to traditional communities.

In 1939, President Lázaro Cárdenas the founding of the mandated the National Institute of Anthropology and History with the responsibility to protect the nation's patrimony and to help the federal government to promote their economic and social welfare programs. The preservation of Mexico's heritage has been bounded, for more than a century to economic growth. To create economic value from Mexico's heritage, President Cardenas considered the fostering of tourism as a viable economic activity for heritage preservation and poverty reduction, as with it comes the need to create services and goods, stimulating employment (López Varela 2014a). This "business model" determined archaeologists to be the only professionals to have the right qualifications to excavate the "ruins" of Mexico and to promote its rich history, qualifications acquired back then, at the Anthropology Department of the School of

Biological Sciences of the *Instituto Politécnico Nacional*, and since 1946, at the National School of Anthropology and History (Escuela Nacional de Antropología e Historia-ENAH). The "Escuela" is mostly responsible for educating students in archaeology, even though the discipline can be studied at public universities. During his presidential term, Miguel Alemán mandated the creation of the National Indigenous Institute (Instituto Nacional Indigenista [INI]) and the National Institute of Beaux Arts and Literature (Instituto Nacional de Bellas Artes y Literatura [INBAL]) to promote further assistance in the modernization of the nation and the management of heritage resources. The institutionalization of Mexico's heritage preservation included the foundation of the National Museum of Anthropology in 1940, by President Manuel Ávila Camacho. The Museum moved to its current premises in 1964.

The national heritage preservation model guides the practice and learning of archaeology and anthropology in Mexico. This model vests INAH to conduct most archaeological excavations, conservation and preservation activities, as well as, salvage work in Mexico. INAH oversees 120 museums, more than 100 thousand historic monuments built between the sixteenth and nineteenth centuries, and 29 thousand registered archaeological sites, of which, only 181 may be visited by the general public. INAH looks after Mexico's World Heritage sites (N: 34).

Debating Mexico's National Preservation Model

In 2015, the Mexican government created the Secretariat of Culture, disaggregating INAH's original federal mandate by creating the Dirección General de Sitios y Monumentos del Patrimonio Cultural (General Bureau of Cultural Heritage Sites and Monuments), and leaving under its jurisdiction the preservation and restoration of cultural heritage, the issuing of heritage preservation policy, all activities related to site management plans, and the responsibility of following international treaties regarding World Heritage sites (DOF 2016). This is not the first time that INAH has gone through a "federal reengineering." The creation of the National Council for the Arts and Culture (Consejo Nacional para la Cultura y las Artes-CONACULTA) in 1988, restrained the federal responsibility of the "Instituto" to preserve Mexico's heritage (Yañez Reyes 2006). In fact, when the government of Yucatan bought the main core center of Chichén Itza from the INAH in 2010, in the midst of a heated debate and indifference by UNESCO, the approved transfer of ownership, set up a different management system to oversee and control heritage resources in Mexico. Having a federal mandated process of heritage management and preservation, invested in a single institution, was one of the strongest assets to protect cultural heritage in Mexico. Although the heritage management process was far from being perfect, it set professional and legal standards for the stewardship of cultural heritage across the country.

Absorbing the full cost of heritage management by the federal government is one of the strongest flaws of having a national preservation model. First, federal budget expenditure among federal institutions is not balanced. Since other federal institutions require more money to support Mexico's sexennial development plan, INAH operates with a limited budget (Paredes Gudiño 2006). Nearly 60% of INAH's annual budget is destined to pay salaries (López Varela 2014a: 83), leaving a very short margin to fund substantial research and heritage related activities (Yañez Reyes 2006: 63) and to contract more personnel to research and protect the thousands of national properties under its custody. The national heritage business model has a low capacity of generating employment, as every job will take a toll on INAH's operational budget. Having a limited budget is detrimental to heritage preservation. Without taking into account, who is responsible for the tragic demolition with heavy machinery of the Chapel of Santo Cristo in the State of Tlaxcala, its destruction demonstrates INAH's limitations to fulfill its mandate in the absence of a budget to contract more personnel to oversee the protection of Mexico's heritage. Limited funding, additionally, has been a major impediment to protect heritage resources against infrastructure development (Carballal Staedtler and Moguel Cos 2007; García Bárcena 2007), one of the main strategies of economic growth.

Finding a solution to budget limitations has stretched the limits of the national heritage preservation model, by allowing the participation of the private sector, an experience that has proved quite unfortunate for the preservation of heritage resources (López Varela 2014a: 83–84). Partnering with a private industry, in the absence of a regulated contracting process of private companies, resulted in the severe damage of the equestrian bronze sculpture of King Charles IV of Spain, casted by Manuel Tolsá in 1802, during its restoration. The unfortunate damage of one of Mexico's downtown historic monuments, which took place without INAH's permission, reveals the uncoordinated and overlapping functions of local, federal, and private institutions to protect and promote Mexico's heritage, introduced by structural reforms, the creation of new secretariats, and private trusts. These actions have taken place without revising their legal frameworks against INAH's regulations.

In Mexico City, for example, INAH shares its federal mandate with Mexico's City Secretariat of Culture (Secretaría de Cultura del Distrito Federal), the authority for downtown's historic center (Autoridad del Centro Histórico), and Mexico's City Historical Center Foundation (Fundación del Centro Histórico de la Ciudad de México A.C.). After UNESCO declared downtown Mexico City a World Heritage Site in 1990, the local government and the private industry established a trust, the *Fideicomiso de la Ciudad de México*, to support the restoration and conservation of its buildings (López Varela 2014a: 84). Now a public entity, the "Fideicomiso," linked to a citizen council headed by business magnate Carlos Slim Helú, who also sponsored the creation of the Historical Center Foundation, contracted the private company that damaged Tolsa's monument.

Increasingly, INAH faces the consequences of infrastructure building. Mexico's citizens have taken to the streets their discontent against INAH's inability to protect their heritage against infrastructure building. Their concept of heritage distances itself from the national definition, as demonstrated by their discontent, during the construction of a COSTCO store on the grounds of the hotel *El Casino de la Selva*, located in Cuernavaca, in the State of Morelos (López Varela 2014b). Its demolition revealed the hidden existence of new forms of valued resources by Mexico's citizens. While building land-use plans for the State of Morelos (López Varela 2014b), the average citizen demanded the preservation of a football soccer court, a movie theater, a hotel, a modern avenue, a shopping mall, or a viewshed.

By promoting culture in UNESCO's terms, INAH contributes to one of the many strategies dictated by world institutions such as the World Bank and the International Monetary Fund, to demonstrate Mexico has reached the needed economic indexes to qualify as a developed, democratic, and sustainable economy. Mexico's need for competitiveness in the global economy has led the government to believe in UNESCO's (2008: 8) promise that, World Heritage sites are "big businesses" with turnovers of millions of dollars a year. Additionally, transnational companies, such as Coca-Cola, are driven forces configuring and marketing the identity of Mexico's national patrimony by supporting INAH's initiative of inscribing sites within UNESCO's World Heritage List. Therefore, Mexico has more World Heritage sites than any other country in the Americas. Unfortunately, heritage sites are not returning the expected revenue. Mexico's limited economic growth can explain the decreasing number of national visitors to archaeological sites between 2015 and 2016. When it comes to visiting archaeological sites and museums in states in which criminal activity is self-evident, there are hardly any visitors, as demonstrated by the available statistics issued by Mexico's Secretariat of Tourism.

Given that Mexico has not transcended beyond a monumental approach to define her heritage, absence from the national preservation model is a legal framework to protect indigenous lifeways and knowledge, against economic growth. The preservation of these fundamental traits of Mexico's national identity is not only threatened by its own model of economic growth, anthropology has been central in their fading away. In supporting Mexico's evident need to alleviate poverty levels and to become a modern nation, anthropologists promoted acculturating policies without coercion. With their support to evaluate those positive aspects of the indigenous lifeways that were to be preserved for the future (Caso

1958: 52), these policies disseminated modern ideas among the indigenous populations, including the use of the Spanish language. The strategy is at the center of the extinction of tongues and dialects in Mexico, and of those lifeways that the government wants so much to preserve as part of her identity.

The problem does not end here. Mexico's indigenous populations have been considered the face of poverty. It is assumed that indigenous populations live in rural areas with less than 2500 inhabitants. When this number is exceeded, they can no longer be the recipients of social development policies to alleviate poverty and promote welfare. Their perception of being indigenous, as a proxy for the allocation of resources, is not a strong solution. There are communities that do not understand the word indigenous, nor does it constitute part of their identity. At Cuentepec in the State of Morelos (López Varela 2010), the population stated they are Mexicans, because they speak *Mejicano* the local native tongue. The appropriation of the indigenous identity, however, is slowly permeating in the community through the introduction of development policies. The population understands they are indigenous because "they say we are," "we are poor and speak náhuatl," or "it is predetermined by the *indigenistas* that we are" (López Varela 2012, 2015).

Learning from Other Models of Heritage Management

Many countries around the world have developed a heritage industry to effectively preserve cultural heritage and to contribute to economic growth through the business of archaeology, mostly, as a response to the strategies of economic growth and development. The American Cultural Resources Association, a national trade association in the United Sates, sets standards to its 1300 firms private firms of all sizes. While advocating for the shared ideals of the industry, these private firms employ nearly 10,000 professionals, including archaeologists, historians, architects, and architectural historians. Together, they generate an annual revenue of almost 1 billion USD.

Mexico is one of the few countries left without a private heritage industry, even if the government believes in heritage as a proxy for economic growth and development, and INAH has given the first steps to assign the responsibility to protect Mexico's heritage to the private sector. Indeed, expanding the differentiation between responsibility and the activities of compliance leads to more effective ways of protecting heritage resources over the national model approach. The emergent partnership with the private sector alleviates the federal government to absorb the full costs of heritage management. Private entities have been permitted by INAH to conduct many of its activities, as demonstrated by the numerous projects funded by Roberto Hernández Ramírez, a well-known banker, serving as international member of the Federal Reserve Bank of New York. Still, the government has to find a way to shift the benefits of this emerging model beyond Mexico's wealthiest citizens and transnational companies and to create working opportunities for her professionals trained in the protection of heritage resources.

In the absence of a process to regulate the quality of the intervention of private companies and their responsibilities, Mexico's government and citizens will continue to pay the price for their mistakes. The damage to the equestrian sculpture by Tolsa is an interesting case in which the government and its citizens, through tax revenue, had to pay for the restoration, not the private company that caused its damage. Since the Organization for Economic Co-operation and Development recommended its members to measure the benefits and adversities of a proposed development project on the environment in 1972, Mexico adopted the recommended polluter pays principle (PPP), in which the developer is responsible for allocating the necessary funds to protect natural resources from development policies or actions by a federal institution or a private contractor. The PPP is the driver financing the CRM industry. Any action by a private or a government entity that has the potential to have an impact on the preservation of heritage resources needs to be measured and the costs of the preservation absorbed by the entity. The PPP does not rule heritage preservation in Mexico and it should.

Creating value from heritage, however, requires a structural change, breaking with past trends and theories, and the ways the Mexican government understands a business economy and projections. When cultural heritage is reduced to an aesthetic dimension for entertainment and not for increasing human capital through the knowledge of history (Montella 2015: 1), it is difficult to create economic value from heritage. The idea that Mexico could create economic value from its rich cultural history by offering it to the tourist industry is no longer a viable option. Mexico is facing high rates of violence and criminal activity. Therefore, cultural heritage is hardly a source of wealth and a magnet for tourism, failing to stimulate spending and to create jobs (López Varela 2014a).

Economic growth is forcing a revision of Mexico's heritage definition and management process and legal background. Moving away from an eighteenth-century approach to heritage and management might be the healthiest way to end the constant unrest and conflict during infrastructure planning and building. The people of Mexico must have a saying as to what is important to preserve, and their voices must not be subordinated to national and international institutions and expert knowledge deciding what their values and traditions must be. There is much to learn from the international experience of adopting a social approach to archaeology and the private heritage industry. In other countries, the applied sector is concerned with the preservation of heritage values in contemporary societies that include a wide range of properties, usually defined, without temporal limits, location restrictions, and scales of significance. Excluding the understanding that tomorrow's archaeological sites are being created today, that history is happening now, and that the material expressions of modern life are the cultural heritage of the nation's future is of great tragedy to the nation, as there are hardly any "material records" of her modern history under the national model approach.

Future Directions

Reaching high growth economic levels requires the Mexican government to follow policies and regulations established by major institutions around the world. Most of these institutions provide Mexico with significant loans to reduce poverty levels and to increase its GDP. Most loans now require the submitting of development plans and management instruments to protect the environment, by considering social, economic, political criteria. Most doing the job in Mexico have been trained in environmental or biological sciences, with hardly any experience in heritage compliance. Mexican archaeologists are not fully trained in compliance, as their skills concentrate on studying the past. The future professional in archaeology requires a different training profile that the current educational model is unable to accommodate and to contribute to these new specifications. In the absence of local expertise, international environmental companies are offering their services to companies investing in the energy sector in Mexico and are capturing the revenue.

Adding to the pressures of Mexico's desire for economic growth, the World Bank (WB) and the Inter-American Development Bank (IDB) have understood that social pressure could affect its performance and profit. The World Bank approved the new Environmental and Social Framework in 2016, reinforcing its commitment to sustainable development in ways Mexico is simply not prepared to meet. Considering indigenous peoples and cultural heritage as part of the "Framework," the World Bank wants to ensure its projects enhance opportunities for indigenous peoples, by stating in their safeguards their right to participate and benefit from development, in ways that do not threaten their unique cultural identities and wellbeing. The World Bank requires a people-focused approach to mitigate the adverse impacts of its projects. This is exactly the opposite of how Mexico's institutions have operated for more than a century.

The IDB states it will not support operations that, in its opinion, significantly convert or degrade critical natural habitats, or that damage critical cultural sites. Its safeguards introduce a definition of heritage based on four values, not entirely included in Mexico's legislations. When assessing the value of a cultural heritage site or object, the IDB (2015) requires "value to communities," as an attribute to be taken into consideration in developing a project. Even if the "Institute" was an active participant in the elaboration of the IBD

safeguards, the "Ley de 72" dismisses alternative views of what heritage means to society. Requesting a loan from the IDB or the World Bank will eventually force the Mexican government to face the limitations of its national preservation model. The Mexican government is under pressure to change its current approach to heritage and its disassociation from people's values. The Mexican government will soon understand that attachment to place is the basis of social identity, that community engagement will enhance sustainability, that heritage is not only constituted of old and pretty things, but involves feelings of association and human emotions, and that embracing this definition is the way to bring significant revenue to the Mexican economy.

Introduction

A growing number of museums and other institutions involved in archaeological and paleontological research are acquiring or developing 3D imaging systems based on X-ray microcomputerized tomography (microCT) (Fig. 1). This X-ray technique evolved from conventional clinical CT scanning, with more than two orders of magnitude increase in space resolution and a great enhancement in image contrast. The past 20 years have witnessed advances in X-ray microCT as a result of advances in X-ray sources (microfocus tubes and synchrotron radiation), 2D detectors (charged-coupled devices, flat-panel detectors, and silicon microstrip sensors), and front-end microelectronics for data acquisition. Advances in computer processing speed and storage memory capacity have also been crucial for the progress of microCT.

MicroCT can reveal, with a resolution down to less than 1 μm, the inner microstructural features of fossil remains and artifacts in archaeological studies. Analyses can be applied to a variety of "hard" materials, such as fossil human teeth and bones; artifacts in metal, glass, ceramics, and stone; and "soft" materials, such as textiles, wood, and paper. Each kind of material requires a different analytical strategy. In particular, effects due to the high dose delivered to some materials of interest, such as the teeth and other precious ancient human remains, should be minimized as they could preclude further analyses. MicroCT scanners are available commercially, but some groups are developing dedicated systems, specifically designed for applications in archaeology, paleontology, and cultural heritage, with space resolutions from submicron, for small mm-size objects, to tens of microns for 10–20-cm-size objects. Portable systems for very large objects (e.g., archaeological objects that cannot be easily moved from the museum) have been designed or are being planned.

Microcomputerized Tomography (MicroCT) in Archaeology, Fig. 1 The microCT dedicated to cultural heritage and paleoanthropology at the "Abdus Salam" International Centre for Theoretical Physics in Trieste, Italy. The system is equipped with a microfocus X-ray tube (*left*) and a flat-panel sensor (*right*). High-precision horizontal and vertical stages allow fine movements and precise alignment of the sample (Tuniz et al. 2013)

Paleoanthropological specimens include human crania, teeth, and postcranial bones, with ages from the Miocene to the Holocene. Other analyses of archaeological interest involve Paleolithic flutes, ancient mommies, stone tools, and wooden statues.

Definition

Computerized axial tomography (CAT) was developed in 1972 by Godfrey Hounsfield and Allan Cormack, who received the Nobel Prize in Physiology and Medicine. CAT devices are based on the use of multiple radiographies taken from different angles around a single axis of rotation. In a conventional CAT, the X-ray source is rotated around the part of the body to be imaged, while the X-ray sensor is positioned on the opposite side. Each radiography thus obtained is based on the absorption or scattering of the primary beam by its interactions with the constituents of the object. The transmitted beam intensity follows an exponential law depending on the linear attenuation coefficient (related to the atomic number and density of the sample constituents) and the sample thickness. Hundreds of radiographies are stored in the memory of a computer and 3D images, including slices of internal parts of the body, are then reconstructed using mathematical algorithms. The most common technique is the "filtered back projection," based on mathematical methods developed in 1917 by the mathematician Johann Radon. Medical CAT systems, often using a spiral scan, have typical resolutions of 0.5–0.3 mm, which is insufficient in many applications of interest to archaeology, where structures on the microscale can be of high interest.

MicroCT was developed in the late 1980s (see, e.g., Feldkamp et al. 1989) using microfocus X-ray tubes, image intensifiers, and cone-beam reconstruction. In these systems, the X-ray source/detector system is kept fixed, while the sample is rotated at various angles. Thousands of digital radiographies are taken using an advanced detector that combines a scintillator and a CCD camera or a flat-panel detector. X-rays penetrate the sample and are detected by a scintillator, which converts them into visible light. Projection images are magnified by microscope optics and digitized to reconstruct 3D images. As for planar imaging, microCT can be performed either in absorption or phase-sensitive modality (in edge detection or in holography regime), depending on the sample-to-detector distance. Resolutions of a few microns (sometimes down to few tenths of micron) can be achieved with these systems, but there are limitations due to the polychromatic X-ray spectrum.

The use of third-generation synchrotron radiation sources offers particular advantages in microCT imaging. The use of monochromatic beams is important for limiting the "beam hardening" effect, often a serious limitation for conventional polychromatic X-ray sources in the analysis of archaeological samples, particularly fossil bones and teeth. This artifact is produced by the low-energy X-rays of the spectrum, which are more absorbed in the sample than the high-energy ones, producing images with brighter sample borders. This effect is stronger in highly mineralized fossils.

Moreover, the high spatial coherence of the X-rays allows the application of phase-contrast techniques. This method is important for imaging samples with structures made of materials with small differences in their attenuation coefficients, indistinguishable using absorption imaging. Fossilized materials have a very small absorption contrast and benefit from the analysis with phase-contrast techniques.

Three-dimensional imaging of specific elements can be obtained by combining microtomography with X-ray fluorescence induced by a scanning micron-size beam (micro-XRF). The development of these methodologies is based not only on the availability of third-generation X-ray facilities but also on recent advances in computer technology, both in terms of processing speed and memory availability, considering that images corresponding to many gigabytes of data can be collected in few minutes of irradiation time.

Transportable microCT systems are becoming available thanks to progress in compact X-ray detectors and electronics, allowing in situ nondestructive analysis of archaeological materials. They can be used in museums to study precious and non-movable objects (Morigi et al. 2010). MicroCT systems based on polychromatic microfocus X-ray tubes can be used for phase-contrast imaging (Wilkins et al. 1996).

Key Issues/Current Debates/Future Directions/Examples

MicroCT is opening a new era in paleoanthropology (Fig. 2), where hominin remains can be finally studied "nondestructively" (this point will be further discussed below) (Mazurier et al. 2006; Tafforeau et al. 2006, Macchiarelli et al. 2006). It is now possible to reconstruct virtually their skulls, extracting them from the rock matrix and correcting for possible plastic distortions. The resulting data are the base for modeling ontogenic processes and biomechanical properties on different skull elements, including the endocranium, maxilla, ear labyrinth, and hyoid bone. Quantitative studies of specific internal structures are possible with the use of advanced mathematical tools, including finite element analysis. Information of crucial interest for evolutionary studies includes quantitative analyses of the enamel and dentin. MicroCT has been also used to check collagen preservation in fossil bones, before the use of invasive methods such as those required for radiocarbon dating (Beck et al. 2012).

Microcomputerized Tomography (MicroCT) in Archaeology, Fig. 2 Juvenile Neanderthal mandible from Molare, with the *lower-left* second deciduous molar virtually extracted and the tooth tissues of this same element showed by transparency (Tuniz et al. 2012)

MicroCT has been proposed as the technique of choice for creating a depository of "virtual" stone tools that could be shared by scientific groups interested to study human behavior. Imaging capabilities based on microCT are introducing "virtual anthropology" as part of the general strategies for the preservation, management, and promotion of natural history collections. This will also offer novel pedagogical approaches for schools and the public (Balzeau et al. 2010).

M

Examples of Special Analyses

A cave bear femur with two holes was found in 1995 in the Middle Paleolithic layers of the Cave Divje Babe I in Slovenia. The bone was interpreted as a Neanderthal flute, but some scholars firmly rejected this hypothesis, on the basis of taphonomic observations, suggesting a carnivore origin for the holes. MicroCT analyses (Fig. 3) show that originally there were four holes and that a thin bone layer was removed in correspondence of the holes, suggesting a possible human intervention for facilitating perforation. It was concluded that we couldn't yet rule out a Neanderthal manufacture (Tuniz et al. 2011).

Stone artifacts provide valuable insight into the evolution of human behavior and cognition. The use of CT scans to create 3D models of stone tools opens the broad access to information about lithic technology and typology and allows the critical assessment of the human or natural processes involved. The efficacy of microCT for visualizing

flint artifacts was tested using a single flake and a refitting group of flakes with a laboratory microscanner (Abel et al. 2011), showing all the advantages of the technique.

The characterization of prehistoric pottery fragments presents a quite complex task. In provenance studies, petrographic and chemical analyses of the ceramic materials are employed to investigate potential production areas in respect to the geological background. Moreover, also the production technology of the firing process, as well as the forming techniques used by the prehistoric potters, is of great interest. Ceramic fragments from the late Mesolithic to Neolithic site Hamburg-Boberg 15 (northern Germany) were analyzed by X-ray microCT, combining quantification and shape analysis of fabric components by means of computer-aided image processing (Kahl and Ramminger 2012). Recently, a new class of metal-imitating pottery has been described using SR microCT and an accurate use of data treatment algorithms (Agostino et al. 2016). Furthermore, the microCT method permits the characterization of the connectivity within the porous system, as well as the analysis of the orientation of the pore structures, which are indicative for vessel-forming techniques.

During burial in soil, archaeological glasses develop corrosion phenomena, which might be represented by a thin surface layer in the range of nanometers up to a few millimeters. Degradation may affect the fragment homogeneously, or it may be concentrated to spots and local cracks. Depending on the impact of different environmental situations (soil, humidity, pollutants, microorganisms), the corrosion process leads to significant changes in the chemical composition as well as to a change of the morphology of degraded areas and layers. Due to the high material contrast of phase-contrast X-ray microCT, a number of interesting phenomena have been visualized in the reconstructed tomograms. Defects inside the glass and the corrosion layers, including thin laminated substructures, have been resolved. For the characterization of treated samples after conservation, moreover, the penetration of a coating or a consolidant into the micro-cracks of the corrosion layer needs to be controlled in order to guarantee a suitable adherence between the polymer and the surface of the glass object. Since conventional microCT is not able to detect a low-absorbing material inside a high-absorbing material such as glass, phase-contrast microCT has been used for this application, and a thick organic polymer coating and a comparatively thin inorganic coating applied on a fairly corroded glass surface could be visualized (Gerlach et al. 2006).

Archaeological wood, and waterlogged archaeological wood in particular, is almost always characterized by a modification in the original properties and structure of the wood. Degradation agents can be of different origins (biological, chemical, physical), and they are able to produce a large variability in the degradation of individual pieces, requiring their characterization for a proper conservation. X-ray microCT is a powerful tool, which provides three-dimensional information on the morphological characteristics of materials.

Furthermore, by means of suitable algorithms, it is possible to reconstruct a volumetric map of X-ray linear attenuation coefficient. X-ray microCT has been applied to the characterization of archaeological wood (Fig. 4) for the investigation of anatomical structure of wood (i.e., determination of wooden specie) and the assessment of wood degradation through the measurement of residual density (Dreossi et al. 2010) (Fig. 3).

MicroCT analysis is defined as a "nondestructive" technique, as X-ray scanning does not produce visible structural damage to the tissue of the specimen. X-rays interact with the atomic electrons of the material, mainly via photoelectric and Compton scattering, with the release of energy in the tissue (called absorbed dose and measured in gray). These ionization effects become evident in case of submicron imaging of the teeth using powerful beams such as those produced by the European Synchrotron Radiation Facility (ESRF) in Grenoble (France), which can cause temporary darkening of the tooth surface. The ESRF scientists suggest to

Microcomputerized Tomography (MicroCT) in Archaeology, Fig. 3 (**a**) Volume renderings of the "Neanderthal flute" (40-mm voxel size), showing the inner morphology for the holes. (**b**) Ten virtual transverse slices through Part III of the "flute" (Tuniz et al. 2011)

use UV light to restore the original color of the enamel (Tafforeau and Smith 2008). Further studies are in progress to understand the structural damage of the fossil teeth and bones by the ionization effects of X-rays, particularly for synchrotron radiation (Richards et al. 2012). In any case, possible damages, even if only at the microscopic level, are creating anxiety in museum curators. The progress in paleogenetic studies is increasing the value of paleontological collections stored in natural history museums, which should be preserved as much as possible in the original conditions and remain available for future generations of scientists.

A high dose is absorbed in the material during the relatively long scanning time (up to several

Microcomputerized Tomography (MicroCT) in Archaeology, Fig. 4 A three-dimensional rendering of recent (**a**) and archaeological (**b**) oak (Dreossi et al. 2010)

hours) needed for the analyses, orders of magnitude higher than with medical CT. For example, the microCT analysis of a tooth can correspond to doses of several hundreds' gray that could be of thousands' gray when synchrotron radiation is used. The irradiation effects on ancient DNA from Pleistocene bones have been investigated using known dose levels (Immel et al. 2016). The study concludes that conventional microCT does not produce effects that would impair future genetic analyses, while synchrotron microCT could degrade the DNA significantly. In this case, some protocols and rules should be followed.

No quantifiable increased DNA strand fragmentation has been shown in bird skins preserved in museum, more than 100 years old, after standard CT scanning. The effect of X-ray irradiation could not be separated from the variability of pre-CT DNA fragmentation in different samples, caused by different preservation conditions (Paredes et al. 2012).

In crystalline structures, such as apatite in the tooth enamel, X-ray-induced ionization causes electrons in the crystal's atoms to jump to higher-energy states, remaining captured in electron "traps." When this effect is strong, as in the case of microCT, it precludes electron spin resonance (ESR) dating, based on the measurement of trapped electrons related to natural radioactivity effects, one of the few dating techniques that can be used to date directly human fossils with ages beyond the radiocarbon limit (Grün et al. 2012). Similar effects should be taken into account for other materials, such as ceramics, that can be dated with thermoluminescence.

Midden Cultivation

Erika Guttmann-Bond
Department of Archaeology, History and Anthropology, University of Wales, Trinity Saint David, Lampeter, Carmarthenshire, UK

Introduction

Midden cultivation is an agricultural method which blurs the boundaries between horticulture and agriculture. The concept of midden cultivation was first suggested by Ritchie (1983), Macphail (1990), and Barber (2003), based on findings of flattened middens which (in some instances) overlay prehistoric plow marks. The practice of cultivating middens in situ was identified with greater certainty in the course of a geoarchaeological Ph.D. project (Guttmann 2001) which sought to analyze middens and associated buried land surfaces on multiphase sites in Orkney and Shetland, UK.

Definition

Midden cultivation is the cultivation of a midden or compost heap in situ, as opposed to the more usual practice of taking composted material from a midden and spreading it onto gardens or fields. The practice is identified by the following indicators:

1. Middens (rubbish heaps) which have been flattened and spread out, sometimes over large areas
2. The presence of ard marks (prehistoric plow marks) within or beneath the midden
3. Characteristics that link the soil within the plow marks with the overlying midden, e.g., where both deposits have a similar ash content, soil chemical signature, particle size, or inclusions such as charcoal, charred peat, or unburnt peat
4. The presence of unusually large charred cereal remains, indicating an exceptionally fertile soil

The more indicators are present, the more probable it is that midden cultivation was practiced.

Key Issues/Current Debates/Future Directions/Examples

Discovery

The concept of midden cultivation was formulated following the discovery of extensive areas of flattened midden material on the Neolithic site of Knap of Howar, Papa Westray, Orkney (Ritchie 1983). In the first phase of activity, around 3500 BCE, a midden up to 40 cm thick was deposited. In the second phase, structures were built on top of the midden and a distinct, upper midden deposit associated with the structures was then accumulated. Both the upper and lower midden deposits had level surfaces, and the excavator suggested that they might have been cultivated. The midden material was quite extensive, covering an area of c. 500 m^2 (Ritchie 1983). Links of Noltland, Westray, is another site with an extensive area of possibly cultivated Neolithic midden, measuring at least 210 by 70 m (Clarke et al. 1978). Cultivation of a midden in the Neolithic was also suggested by Macphail (1990) at Hazleton North, Gloucestershire, where small, shifting arable plots were recorded beneath a Neolithic long

cairn and one of the plots was placed on top of a midden heap.

Tofts Ness and Old Scatness

Midden cultivation was more firmly identified during the course of a geoarchaeological investigation of two multiphase sites in the Northern Isles of Scotland (Guttmann 2001, 2005; Guttmann et al. 2004). The evidence was derived from two multi-period sites: Tofts Ness, on the Isle of Sanday, Orkney, and Old Scatness, near the southern tip of Mainland, Shetland. The Tofts Ness site dates from the Neolithic to the Early Iron Age (Dockrill et al. 1994), and Old Scatness dates from the Bronze Age to the present, although it was not necessarily occupied continuously (Dockrill 1998). The two sites are in regions which (before stabilization of the dunes) were subject to major episodes of sand blow, and these sand deposits periodically buried and preserved successive agricultural soils together with the associated settlement evidence. At Tofts Ness, radiocarbon-dated Neolithic middens overlay a cultivated Neolithic soil, and at Old Scatness the earliest soil, dating from the Bronze Age to the Iron Age, was buried beneath Iron Age deposits. There were ard marks below both of these early soils (Guttmann et al. 2004).

The two sites were investigated in order to identify changes in agricultural methods over time (Guttmann et al. 2004). A range of geoarchaeological methods were employed in order to identify materials in the soils and middens, with the aim of identifying possible fertilizers used in the fields or accumulated in the middens. The methods included thin section micromorphology, phosphate analysis, soil magnetism (mass susceptibility, frequency-dependent susceptibility, anhysteretic remanent susceptibility, and isothermal remanent susceptibility), loss on ignition, and particle size analysis.

The results of the thin section analysis, phosphate analysis, and particle size distribution demonstrated that the arable soils were composed of exactly the same material as the midden heaps (Figs. 1 and 2). Unlike the soils of later phases, these were not simply soils with added compost but actually represent middens which were cultivated in situ (Guttmann et al. 2004; Guttmann 2005). The material which infilled the ard marks on both sites was clearly the same as that which overlay them, which demonstrates that the ard

Midden Cultivation, Fig. 2 Iron Age soil and midden in thin section under oblique incident light. Old Scatness, Shetland

marks did not predate the layer above but were contemporary with it.

The evidence suggested that the arable plots were placed on top of the midden heaps, that is, the midden heaps were transformed into cultivated plots. The cultivated midden formed a small plot at Tofts Ness; the extent is unknown but the midden soil was not found in surrounding test pits, which suggests that the plot was no more than c. 10 or 20 m^2 (Guttmann et al. 2004). At Old Scatness the midden field may be more extensive; subsequent excavations on the opposite side of the Old Scatness settlement mound have produced more cultivated middens, probably of the same Bronze Age to Early Iron Age date.

Midden Heap Cultivation

Midden cultivation also may have occurred in the Western Isles of Scotland, where large amounts of midden material have been identified interleaved between the machair sands on several sites. Gilbertson et al. (1999) established that Bronze Age and Iron Age buried soils in the machair at Cill Donain, South Uist, contained large amounts of midden material and represent anthropogenic activity rather than periods of natural dune stabilization. It is possible that some of these deposits were cultivated middens rather than natural soils with added midden material. Midden material was also deposited over large areas on the Bronze Age/Iron Age sites of Baleshare, North Uist, and Hornish Point, South Uist (Barber 2003). Midden material was dumped onto the soil to create arable plots at Baleshare, but at Hornish Point the author suggests that the Iron Age midden deposits were probably cultivated in situ (Barber 2003).

The cultivation of the midden heaps at Tofts Ness and Old Scatness is indicative of a small-scale but intensive land management system. The enriched soils would have been an important resource, which suggests long-term occupation or repeated reoccupation of the sites. The extent of the practice is not yet clear; monumental middens in southern England, such as those found at Runnymede and Potterne, would seem to be potential sites for midden cultivation, but there is no clear evidence for this to date.

Neolithic Cultivation of Mesolithic Middens?

Recent work at Northton, Harris, in the Outer Hebrides, suggests that people in the Neolithic may have cultivated earlier middens as well as those of their own creation. The site at Northton was originally excavated in the 1960s and

comprises a series of midden deposits and structures; the pottery indicated a Neolithic to Beaker period chronology. The site was re-excavated in 2000, but despite the recovery of a Neolithic potsherd, a grain of barley and a sheep phalanx (all of which indicate a Neolithic date), hazelnut shells within the midden produced Mesolithic dates (7050–6650 cal BCE and 6450–6200 cal BCE) (Simpson et al. 2006).

A thin section analysis of the deposits at Northton indicated that the midden layers contained large quantities of added anthropogenic materials (Guttmann 2006). The cultural materials (mainly bone fragments and charcoal) occurred throughout the midden deposits, including in the basal layer and the glacial till below. This means that the midden did not seal an undisturbed buried soil, which suggests that the original soil must have either been removed (unlikely) or reworked (very probable). It was evident in thin section that the deposits were intensively reworked by earthworms, but it is also possible that the deposits were cultivated. This would explain why there was no distinct buried soil predating the midden, and it would explain the absence of soil-forming processes within the midden deposit, and it would also explain the presence of Neolithic material in a Mesolithic midden.

Northton is not the only Mesolithic site where later cultivation may have taken place. A Mesolithic midden located near Prestatyn, on the north coast of Wales, also appears to have been cultivated in the Neolithic (Guttmann 2005; Bell 2007). The midden comprised two layers, the lower dating to c. 4550–4230 cal BCE and the upper to c. 4250–3700 cal BCE. The lower, Mesolithic layer contained dense mussel shell, while the upper had much lower quantities of shell and appeared to have been reworked. Lines of shell extend out from the midden and appear to have been dragged by an implement. These lines are interpreted as possible ard marks.

The recovery of Neolithic material in Mesolithic middens is a common occurrence in Scotland and has previously been interpreted by some as evidence for the continuity of a marine-based economy into the Neolithic period (e.g., Armit and Finlayson 1992). Others argue that there was a radical change in diet in the Neolithic, indicated by a change in the isotopic signature of the human bone (Schulting and Richards 2002).

The evidence from Northton and Prestatyn suggests a possible way of reconciling this apparently conflicting evidence for continuity and change in the Neolithic economy. The attraction of the rich midden deposits may explain why Neolithic people chose to settle on sites that were previously occupied by Mesolithic peoples. If, as is suggested by Schulting and Richards (2002), the Neolithic diet was wholly or almost wholly terrestrial, it begs the question of why terrestrial farmers would reoccupy places which were presumably sited in order to exploit marine resources. If the Neolithic people were not using marine resources, what was the attraction of these sites? The obvious fertility of the middens may have been a key factor. The vegetation growing on the middens would have been distinctively richer than the vegetation produced by the surrounding soils, and this would have been readily apparent to the early farmers.

The extent of midden cultivation outside Scotland is unknown. In Scotland the post-Mesolithic middens are often easy to identify because they tend to contain large quantities of peat ash, which has a distinct yellow or orange color in the field. Under the microscope in thin section samples, the ash constituent is even more obvious, glowing bright orange under oblique incident light (Fig. 3) (Guttmann et al. 2004). In regions where

Midden Cultivation, Fig. 3 Peat ash in thin section under oblique incident light

middens are less distinct, it may be more difficult to distinguish cultivated midden from garden soils with large amounts of added fertilizer.

Middle East Archaeology: Sites, Texts, Symbols, and Politics

Sandra Arnold Scham
Center for International Development and Conflict Management, University of Maryland, College Park, MD, USA

Introduction

Though the story is most certainly apocryphal, the first recorded incident in which archaeology provided the symbolic ammunition for political ambitions occurred in 550 BCE. The leaders of the legendary warriors of Ancient Sparta sought to expand their tiny kingdom to include richer farmlands elsewhere in their region. The Spartans had long had their eyes on Arcadian Tegea but, after many attempts, had never been able to conquer it. The Oracle at Delphi prophesied that they would not win the lands of Tegea unless they were able to dig up the bones of Orestes. They were told that the bones rested in Tegean soil, and through a chance meeting with a local smith, a

Spartan warrior discovered that the skeleton of the ill-fated son of a Homeric hero could be found in a field not far from the city. The Spartans went to the described field, dug up the bones, and won the day (Hall 2007: 333). Texts, sites, and symbols of the past have been in play for the causes of politics ever since.

Definition

Archaeology is seldom considered as a part of military strategy or foreign policy, except to the extent that, in modern war zones, world heritage sites sometimes have greater protections than civilians. The past and representations of the past, however, are clearly part of those elusive elements, which include charismatic leadership, morale building, and the incitement of nationalist, ethnic, or religious fervor, that go into the making of successful wars, insurgencies, and revolutions both ancient and modern. This is unanticipated by scholars of the past unless they have been directly ordered or inspired to find evidence that will fuel the reigning ideology. It is more often the case that the political value attached to a site or object is a later development. Even in the case of decidedly nationalist archaeological endeavors, the most potent emotional and political connections are usually established long after the projects are finished.

Key Issues

Yigael Yadin's excavations of Masada in Israel or Manolis Andronikos' excavations of Vergina in Northern Greece are examples of this phenomenon. Yadin, of course, knew that Masada, representing the putatively suicidal last stand of Jews against Ancient Romans in 75 CE, was highly significant in Jewish history. He did not necessarily predict that it would become the favored spot for inducting soldiers into the Israeli Defense Forces for many years (Silberman 1994). Similarly, Andronikos may have seen Vergina, with its purported tombs of Philip of Macedon, Alexander the Great's father, as an important Greek heritage site, but he would be surprised to find that the famous symbol he unearthed on a sarcophagus there, the Star of Vergina, became a subject of great contention between the neighboring modern nations of Greece and the Republic of Macedonia (Cowan and Brown 2000).

The recognition that many sites and symbols of the past represent continuing struggles in the present has caused a deepening rift between archaeologists working in areas of enduring ethnic strife and those who work with well-funded governmental and academic institutions on recovering, preserving, and presenting sites in more stable countries. While the former tend to be more concerned with critique, the latter tend to focus on preservation, authenticity, and recognition of living descendant communities. This may be due to the fact that political instability creates uncertainty about the future of the sites and their material culture. The meaning of the past(s) that these scholars would like to relate to modern populations may, thus, be subject to over-politicization in the hands of one group and over-homogenization in the hands of the other.

The convoluted process by which a site or artifact becomes a powerful symbol for a political or social movement involves a number of factors over which archaeologists have little or no control as well as those over which they have great control. Nationalist and imperialist archaeologies may be the impetus for the excavations that produce these symbols – or their significance may simply grow organically as the society itself develops and grows more complex. What is universally true about the relationship between archaeology and politics, however, is that it is both materially and ideologically formed outside of the science of excavating and interpreting sites, particularly in the case of sacred space.

Examples

"A thing belongs to the one who remembers it the most obsessively," as Makiya has said about the Dome of the Rock in Jerusalem (Makiya 2001: 266). Creating obsessive memory is not the province of archaeologists but the close relationship

between living traditions and events far in the past in the Middle East means that archaeological endeavors there, particularly with respect to sacred sites, will have an unexpected immediacy and sometimes even notoriety. Jerusalem is the oft-cited example of a city that combines omnipresent antiquity with intense attachments. The deep-rooted feelings that people from so many different backgrounds have about the city are consistently reinforced by its ancient buildings. Jerusalem is also a place where the often carelessly used expression "world heritage" has a highly significant, and unusually divisive, meaning.

The collective memories of Jerusalem's inhabitants remain as contentious as they are cherished by both sides of the continuing struggle taking place there. Embedded in the collective memory of Jews in Israel is the view that Jerusalem represents an incomplete return to Zion – incomplete because the hill upon which one of Islam's holiest places now sits was the traditional site for the ancient destroyed Jewish Temple (Fig. 1). Embedded in the collective memory of Muslim Palestinians is the belief that Jerusalem establishes a vital connection between them and their co-religionists elsewhere in the Middle East (Scham 2004: 648). Christians from outside of the region find themselves in opposition to each other and sometimes to Christians living within the region, with fundamentalists supporting Jewish claims to Jerusalem while others the claims of Palestinians.

Sites of the past that have religious or nationalist significance for more than one ethnic or confessional group are the foci for hegemonic heritage struggles. These struggles are most often won by those who have control over the site with the memories of other groups effectively blotted out. Hegemonic heritage operates on the principle that if one narrative about the past of a particular place is true, then all others must be false – or worse, dangerous. The fact that permission to use certain sites is furnished to one group but denied to another is not based upon contested histories surrounding the site. More accurately, these sites become battlegrounds because of the necessity for one side to establish its claim and its narrative to the exclusion of all others.

Middle Eastern archaeological sites may also be the scenes of heritage suppression strategies that are designed to tacitly ignore everything that does not benefit the power interests of the present. There are many ways in which such benefits may be defined – but it is generally economic, religious, and political considerations that prevail. In Nasser's Egypt, for example, the country's

Middle East Archaeology: Sites, Texts, Symbols, and Politics, Fig. 1 View of the Old City of Jerusalem with the Dome of the Rock taken from West Jerusalem

rich history was denied and ignored because the Pharaonic past was an impediment to establishing a Pan-Arab identity. Building dams without regard to archaeological sites did not endear him as a leader to Western heritage professionals, but it also turned out that Egyptians themselves were more proud of this past than Nasser had estimated (Hassan 1998), and later leaders of Egypt were only too eager to show off the Pharaonic sites to distinguished visitors. Similarly, Saddam Hussein lavished attention and resources on the cities of the Babylonian Empire but those of the Assyrian Empire were largely left to crumble. He, no doubt, felt far less affinity for the Assyrians because their contentious Christian descendants had been a thorn in his side from the beginning of his regime (Abdi 2008). After Hussein was executed, the Assyrian Democratic Movement was one of the first groups to step forward to vie for power in the country.

Heritage repression may be a favored weapon of autocrats, but in recovering war zones, it becomes a means of survival. Beirut is a city where many decisions about archaeological sites are affected by an implicit agreement that history must be ignored as much as possible. The collective memories of the city's diverse residents have been in conflict for so many years that the best strategy that has been developed is one that involves separating the people from their contentious pasts. The country's multicultural story was laid bare by the destruction of Beirut's downtown during the civil war. Lebanese archaeologists, however, have to continually fight to preserve these remains as the city is being rebuilt as a glittering (and hopefully peaceful) modern example of the "New Middle East" (Lawler 2011).

Current Debates

Sites and symbols are the agents of collective memory, but its structure, at least in the Middle East, is defined by texts. Cuneiform tablets, papyri, scrolls, and inscriptions all have a uniquely privileged status beyond that of mere artifact (Scham 2009: 169). Modern scholars, of course, will not admit to using texts as archaeological source books. They are, nonetheless, an ever-present entity still waiting in the consciousness of many to be put into play in describing finds. This is especially true of the Bible which, despite its dubious historical value, has been used to define the past of Israel, Jordan, and Turkey, and, in part, Egypt and Mesopotamia for generations. Like the *Iliad* and the *Odyssey* in the early years of classical archaeological exploration, the Bible has inspired excavations throughout the region. Unlike the Homeric epics, the biblical text continues to be reinvented for the purposes of explaining the past. Barthes' observation that text is "... experienced only in an activity of production. The Text cannot stop..." (1977: 157) cogently describes the relationship between archaeology and the Bible.

Ignoring the text in that branch of Middle Eastern archaeology still known as biblical archaeology is not an option, as there are few who will be interested in pursuing an archaeology of the "holy land" denuded of its associations with the Bible. Scholars who have attempted to do this to any extent are dismissed by many of their colleagues as "minimalists." Although the term seems to imply a kind of austerely modern approach, even minimalists cannot eliminate any consideration of the Bible altogether in favor of a sites-and-artifacts-centered view. Minimalists and maximalists alike are both equally defined only by their textual approach, and neither group is willing to consider material culture as anything more than evidence that either confirms or contradicts the text.

Another structural use of text arises as a result of the distinction that those who have had the longest experience in working in very overtly politicized environments, biblical and Near Eastern archaeologists, have drawn between their fields and that of anthropological and social archaeologists. The "labels we choose to stick upon the corpse of history" (Hodder (citing Collingwood) 1993: 269) are not created in these archaeologies by material culture. The concept of

"reading" non-textual artifacts as text (Hodder and Hutson 2004) introduced into anthropological archaeology some decades ago is little understood or accepted in biblical and Near Eastern archaeology. The tendency to view text as the primary explicator of archaeological finds is noted by Abu El-Haj (2001) who describes Israeli archaeology as consistently conflating text, dogmatic belief, and practice.

Future Directions

Middle Eastern politics, if not Middle Eastern archaeology, began to veer away from the text, so to speak, in the spring of 2011. As the term text itself became a verb, its full power is being realized in the widespread use of information technology to mount challenges to the ruling powers of Tunisia, Egypt, Libya, Yemen, Bahrain, Syria, Jordan, and Lebanon. That the Arab World has been transformed by young people texting each other has become a modern news cliché. Bible, Q'uran, and historical manifesto notwithstanding, the power of the original is nothing compared to the blogged or tweeted interpretation of it.

What do these social media-stoked revolutions portend for the relationship between Middle East archaeology and politics in the future? It is difficult to assess the uses that new regimes might make of archaeological sites and artifacts. In contrast to the ubiquitous images of Hosni Mubarak as pharoah and Saddam Hussein as Nebuchadnezzar, the images used now are primarily those of Islam and the Islamic Past. This has become the case in Palestinian West Bank as well where a number of biblical sites, once revered by Muslims as well as Christians and Jews, have become symbols of negative heritage to be destroyed and looted as representations of the occupation of the territory by Israel (Yahya 2010).

For every report of site destruction emanating from the Middle East, there is a corresponding report that, even in the midst of armed rebellion, there is also continued veneration of the past. The so-called Treasure of Benghazi disappeared from a bank vault but the rebels who broke into Tripoli's National Museum bent on destruction only wrecked Qaddafi's old cars on display. Looters ran rampant in Egypt but the Supreme Council of Antiquities (SCA) has managed to restore security in most places despite the uncertainty of the country's future. A reported looting epidemic in Tunisia turned out to be an attempt perpetrated by the family and friends of the ousted dictator to make off with valuable artifacts as they left the country (Elkin 2012: 30).

Meanwhile, Israel has hoped to weather the changes being experienced by its neighbors simply by enduring and by continuing its efforts, dating from the end of the Six-Day War, to assert sovereignty over all of Jerusalem. The tremendous post-1967 onslaught of archaeological excavation, attesting to the Israeli government's concern about finding its own truth under the layers of largely Islamic and Ottoman remains in the city, continues in full force. The destruction of the historic Mamilla Cemetery close to the walls of the Old City, with remains of religious Muslims dating back to before the twelfth century AD, is by now almost complete and the construction work on the *Museum to Tolerance* that will take its place has begun.

Middle East Middle to Upper Paleolithic Transitional Industries

Sonia Shidrang
Saeedi Institute for Advanced Studies, University of Kashan, Kashan, Iran
PACEA-PPP- UMR CNRS 5199, Université Bordeaux, Bordeaux, France

Introduction

As in Europe, the Middle to Upper Paleolithic transition is an intensely debated topic in Paleolithic archaeology and paleoanthropology of Western Asia. The Middle to Upper Paleolithic transition was an important period of biological and cultural changes in human evolution. The disappearing of Neanderthals and the expansion of anatomically modern humans in Europe and south Western Asia, as well as the emergence of Early Upper Paleolithic technologies, which signals significant changes between 45,000 and 30,000 years ago, are just some of the enigmatic aspects of this transitional period. It is not clear where the process of the changes initiated or whether it has been diffusion from a core area or local adaptation in different regions. Many researchers point to East Africa and Southwest Asia, in particular Levant, the region that the best documented records come from.

Thus, the Middle East is a key area that always has been the center of attention in the quest for the origin of the first wide speared cultural manifestation of anatomically modern humans. The present entry reviews the Middle to Upper Paleolithic transitional lithic industries as an important part of the material culture related to one of the most crucial stages of human evolution in the Middle East. In this entry, the Middle East is defined as a geographical area from Anatolia and southern part of Caucasus in the North, the Levant to the Iranian plateau in the center and the Arabian Peninsula in the South (Fig. 1).

Definition

During Oxygen Isotope Stage 3, several Middle to Upper Paleolithic transitional entities appear across Eurasia dating back to the interval of 50,000–30,000 BP. These variable entities or lithic industries are traditionally attributed to the end of Middle Paleolithic, the Initial and then Early Upper Paleolithic, with different names such as the Emiran, Bohunician, Szeletian and then early Ahmarian or Proto-Aurignacian.

The Initial Upper Paleolithic refers to industries that often encompass a combination of Levallois-Laminar technologies accompanying Upper Paleolithic retouch tools and sometimes Middle Paleolithic types and generally date to between 45,000 and 36,000 years BP. But the earliest appearances of true Upper Paleolithic characteristics manifest in Early Upper Paleolithic industries such as early Ahmarian or Proto-Aurignacian, with production of blade/bladelet from prismatic cores and emphasis on the soft hammer technique. Better-studied European evidence in particular suggests a relatively rapid and growing process of invention in different aspects of hunter-gatherers life during this time span. Apart from blade/bladelet-based technologies, long distance procurement of raw materials, specialized hunting, complex settlement patterns, bone industries, the common use of personal ornaments and ultimately certain types of art are documented in many archaeological sites. It is the beginning of the process through which anatomically modern humans dispersed widely, and is recorded in the variable industries reported from several regions in the Europe and Southwest Asia. Many of these lithic industries traditionally grouped under the title of Aurignacian techno-complexes and were considered as the marker of anatomically modern human migrations. The scarcity of human fossils from Initial or Early Upper Paleolithic contexts compels researchers to rely mainly on cultural remains and particularly lithic technology, which also seems to be a complex and difficult way to discuss the actual changes during the time of "Transition". The

transition sometimes refers to the technological continuity between Middle and Upper Paleolithic features, and sometimes indicates a probable mixture of Middle Paleolithic elements with Upper Paleolithic ones in other regions. Traditionally, the typo-technological continuities and discontinuities in lithic entities have been used to support the fundamental hypothesis of local evolution versus acculturation in Paleolithic literature.

Historical Background

The concept of Middle to Upper Paleolithic transition was founded in Europe, particularly Western Europe, the place where the Paleolithic archaeology has its formation roots as early as nineteenth century. In the Middle East, this Euro-centric research historically focused on the Levant and then Iran, in particular Zagros. Pioneering works of R. Neuville and D. A. E. Garrod before the mid twentieth century built a unilinear model for Upper Paleolithic of Levant; in the 1970s, it was replaced by a new hypothesis of parallel entities. In the new parallel Upper Paleolithic entities, the Ahmarian concept defined and added to the previously identified Levantine Aurignacian (Gilead 1981; Marks 1981). In the Zagros, the previous work of Garrod in Levant and Zagros inspired the work of other researchers, which lead to the birth of the Baradostian name for the industry found in Early Upper Paleolithic layers of Shanidar (Solecki 1958). Subsequent research in the Zagros tended to attribute of most of the discovered Upper Paleolithic industries to Baradostian, and reject the possibility of its evolution from underlying Mousterian. Based on the similarities observed in Warwasi assemblage, Baradostian renamed Zagros Aurignacian and opened for discussion the probability of its local origin in Zagros Mousterian (Olszewski and Dibble 1994). About a decade earlier in Levant, a crucial notion emerged that the evidence in the site of Boker Techtit indicates the development of the local late Mousterian into earliest Upper Paleolithic (Marks 1983). This earliest Upper Paleolithic was in fact Emiran, the first phase of the Upper Paleolithic unilinear model of Garrod and Neuville, which then recalled Initial Upper Paleolithic and was applied by many researchers to the same industry. Technological study of Yafteh cave lithic collections in Zagros revealed the resemblance of Baradostian early and late phases to the two-tradition model of Levant (Bordes and Shidrang, 2009). Ongoing excavations and research also point to some differences between early Ahmarian and early Baradostian that remain to be described in detail (Otte et al. 2011). Apart from these two key regions that historically received more broad attention, quite recently, increasing research in other parts of Middle East, such as Arabian Peninsula, Turkey or Caucasus, is providing us with interesting information. Some of the results of these researches will be briefly reviewed in the following section, in a region by region framework.

Key Issues and Current Debates

Levant

The important geographical location of Levant at the crossroads of Africa and Eurasia has led to centralization of Paleolithic research in this region, and consequently a better understanding of its Paleolithic cultures. This is particularly true for the crucial period of shift between Middle and Upper Paleolithic. As the result of decades of research, a relatively reliable sequence of cultural traditions has presented in Levant, which has become a comparative reference for neighboring areas.

The earliest Upper Paleolithic of Levant represents local modifications of lithic industries from Late Mousterian into the early Upper Paleolithic tradition of Early Ahmarian. Prior to Early Ahmarian, the best known MP-UP Levantine transitional lithic industry is called the Initial Upper Paleolithic, also known as the Emiran (Marks 1990).

The Initial Upper Paleolithic industries of Levant date back roughly to about 45,000–38,000 BP and present two main variants, one with characteristic index fossil of the Emireh point and the other with the chanfrein pieces. The

Middle East Middle to Upper Paleolithic Transitional Industries, Fig. 2 The characteristic elements of Initial Upper Paleolithic or Intermediate Middle to Upper Paleolithic industries: *1* Nubian Levallois core, *2–3* Emireh points, *4–6*, *12–16* Levallois-type points, *7–11* Chanfreins on faceted blanks, *17–18* Cores. (After Belfer-Cohen and Goring-Morris 2007*)*

technological characteristics of these industries usually include production of non-Levallois blades and Levallois-like points, hard hammer blade production and Upper Paleolithic retouched tools (Fig. 2). Ksar Akil in northern Levant and Boker Tachtit in southern Levant are the best relevant reference sites showing evidence of continuity for the intermediate phase between Middle

and Upper Paleolithic in Levant (Marks 1983; Ohnuma 1988).

The continuity between the Initial Upper Paleolithic and the Early Ahmarian has also been recognized in several sites including those mentioned before (Marks 2003). This continuity is expressed by some similar technological characteristics, exemplified by the continued use of faceting as part of core preparation. The Ahmarian is divided into Early (42,000–30,000 BP) and Late phase (30,000–23,000 BP) and is better known from open-air sites and semi-arid marginal zones. The Early Ahmarian is characterized by the production of blade and bladelet from several types of prismatic cores with the purpose of manufacturing blade/bladelet tools, particularly el-Was points. The other categories of tools, the cortical end scrapers and burins, seem to be also related to the same reduction sequence; their blank produced during the preparations and rejuvenations of blade/let cores (Goring Morris and Davidzon 2006).

The Levantine Aurignacian is another Upper Palaeolithic entity in Levant assigned to about 32,000–30,000 BP (Bar-Yosef and Pilbeam, 2000) and typo-technologically contains classical Aurignacian features. The European Aurignacian seems to present older dates (around 39,000–35,000 BP) and compared to its Levantine counterpart is a longer lived entity. Contrary to Early Ahmarian, which is technologically based on production of straight to curve blade/bladelet, in the Levantine Aurignacian, blades are the dominant blank for tools and there is a production of small twisted bladelets from carinated pieces, while flakes make up the major part of the debitage (Goring-Morris and Belfer-Cohen 2006).

Due to the late, short-lived and geographically limited appearance of the Levantine Aurignacian, it doesn't play an important role in the debate of the Middle to Upper Palaeolithic transition in Levant and is usually considered as a late intrusive culture.

Zagros

The majority of our knowledge for the Iranian Early Upper Paleolithic comes from the Zagros region. Last two decades saw an increasing interest in Upper Paleolithic of the Zagros region, in particular its early phase, which has a potential to answer some of the questions of Middle to Upper Paleolithic transition in Middle East. The resemblance of Baradostian lithic industries of Zagros with Aurignacian technocomplexes in Europe and Levant, and also the hypothesis that it evolved out of underlying Zagros Mousterian, engaged Baradostian as one of the potential candidates for ambiguous origin of Aurignacian. The current information comes from several cave and rockshelter sites, mostly in Iran (except Shanidar cave in Iraq), and more precisely in the intermontane valleys of Kermanshah and Khorramabad in the Western Zagros and a few sites in Fars province in the southern Zagros, which all yielded Baradostian industry. The definition of Baradostian and its affinities to Aurignacian has gradually formed and strengthened since its recognition in 1958 at the Shanidar Cave in the western foothills of the Zagros in Iraq (Solecki 1958). On the basis of similarities observed in Warwasi assemblages and Aurignacian technocomplex, the name "Zagros Aurignacian" suggested for Baradostian and two main chronological phases described for it (Olszewski and Dibble 1994). The earlier of these has been classified as the Early Zagros Aurignacian, and includes a combination of Upper and Middle Paleolithic tools, such as carinated endscrapers, burins, Font-Yves points, Dufour bladelets, sidescrapers, and truncated-faceted pieces. Most of the tools are on flake blanks and some are on blade and bladelet blanks. The debitage is dominated by flakes, but prismatic blade technology is also present. This assemblage has presented as an example of a transitional industry, which can indicate one sequence of development from a Middle Paleolithic into the Aurignacian. Later phase has classified as the Late Zagros Aurignacian and it is most typical for having the characteristic types of the Aurignacian. There is a considerable number of carinated burins and Dufour bladelets, carinated endscrapers as well as Arjeneh points. Tools are made about equally on blade, bladelet, and flake blanks. Technologically, this assemblage is dominated by bladelet debitage (Fig. 3).

The Late Zagros Aurignacian at Warwasi appears to share broad similarity to assemblages of central Europe and the beginning of the Levantine Aurignacian (Olszewski and Dibble 2006). In addition to Warwasi, recent researches of Yafteh Cave, which include restudy of the 1965 collections (Bordes and Shidrang 2009), and new field works (Otte et al. 2007, 2011) yielded a better-defined typo-technological characteristics and more importantly radiocarbon dates for Baradostian (Fig. 4). Based on recent re-studies of lithic material from 1965 excavation, the existence of two main typo-technological phases were described for the Yafteh sequence (Bordes and Shidrang 2009). The lower part of the deposit was associated with an assemblage mainly oriented toward the production of Arjeneh points and relatively large, straight or slightly curved Dufour bladelets. The bladelets or blanks of these tools were removed from prismatic cores or sometimes from narrow flake ridges. There are also a number of end-scrapers on blades, which sometimes have Aurignacian retouch on their lateral edges (Fig. 5). In the upper part of the sequence, carinated burins are dominant and small twisted bladelets were removed from them and subsequently transformed by inverse or alternate retouch into Dufour bladelets (Fig. 6). A series of radiocarbon dates which suggests the attribution of the materials to an age between 24,500 and 36,000 14 C BP. The more recent results indicate a single chronological signal of approximately 33,500 14 C BP for the major part of Yafteh sequence. Radiocarbon estimations

from main occupation of Yafteh appear to pre-date the chronological range of considerable Levantine Aurignacian sequences and overlap some of the Early Ahmarian ones (Otte et al. 2011).

Anatolia

Despite its important key position, Anatolia is relatively less known in the debate of Middle to Upper Paleolithic transition, compared to Levant and other adjacent regions. The major part of our information for this period comes from two cave sites, Üçağızlı and Karain B located in Mediterranean Zone of modern Turkey. Üçağızlı Cave is located on the Mediterranean coast in the Hatay province of south-central Turkey. Radiocarbon dates indicate that the early Upper Paleolithic sequence of Üçağızlı corresponds to the temporal interval between 41,000 and 29,000 uncalibrated radiocarbon years BP. The earliest dates associated with the Initial Upper Paleolithic (IUP) industry, quite the same transitional industries identified in Levantine sites, correspond to about 35,000 and 41,400 radiocarbon years BP. The earliest true Upper Paleolithic entity, which was found on top of IUP layers, is the early Ahmarian known widely from Levant. The dates for Ahmarian layers at Üçağızlı Cave fall within an interval of 29,000–34,000 radiocarbon years BP (Kuhn et al. 2009). This interval corresponds with the earliest time range of early Ahmarian industries at open-air sites in the Sinai and Negev deserts of the southern Levant (Marks 1983; Bar-Yosef and Pilbeam 2000).

Apparently there is a noticeable degree of typological continuity throughout the Üçağızlı sequence. For instance, the endscrapers are the dominant retouched tool forms in all layers and pointed blades are most common in the upper layers and less abundant in the earlier part of the sequence. The technological attributes of

Middle East Middle to Upper Paleolithic Transitional Industries, Fig. 6 Some of the Late Baradostian characteristic artifacts from Yafteh Cave: *1–2* small twisted bladelets, *3–4* dufour bladelets (Roc-de- Combe subtype), *5* carinated core, *6–8* Carinated burin. (Drawing: S. Shidrang)

Levallois method and small numbers of chanfreins are common in IUP of Üçağızlı Cave. The Chanfreins are considered one of the types of fossils of the IUP or Transitional assemblages of northern Levant.

The Levallois blanks, particularly blades and elongated points, are common in IUP layers and their frequency decline over time. Changes in platform morphology and preparation indicate an abrupt shift from hard hammer percussion to soft hammer or indirect percussion at the end of IUP layers, which point out to the shift from IUP to Ahmarian (Kuhn et al. 2009).

The Üçağızlı Cave data supports the records from Ksar ‘Akil in showing gradual changes in lithic industries over time. The features that make IUP a transitional industry are the persistence of some Middle Paleolithic characteristics, such as application of Levallois method, hard-hammer technique and platform faceting, while the assemblage is Upper Paleolithic from typological point of view. The attributed Levallois features may imply that the Levantine IUP industries had their origins in the Middle Paleolithic in Levant or Middle Stone Age complexes in nearby regions.

The Üçağızlı sequence provides evidence for the evolution of IUP into the later Upper Paleolithic “early Ahmarian,” but since there is no evidence of Middle Paleolithic underlying the IUP layers of Üçağızlı, it cannot participate in the debate of Initial Upper Paleolithic origins in the region (Kuhn et al. 2009).

Apart from Üçağızlı, another cave called Karain B in Antalya has yielded a sequence encompassing Middle and Upper Paleolithic remains. The Early Upper Paleolithic in Karain B has been described as an Aurignacian-like industry with carinated and nosed end-scrapers associated with Dufour, Krems type retouched bladelets and carinated burins. Beside an irregular flake production, the retouch blades are present in moderate frequency, but a few prismatic bladelet cores were recovered. The available date for this industry is around 28,000 BP, which corresponds with the latest time range of early Ahmarian industry at Üçağızlı cave. The underlying Middle

Paleolithic artifacts display the typical characteristics of Mousterian industry, including Mousterian points, side scrapers, notches, etc., quite similar to those found in Zagros (Yalçınkaya and Otte 2000). Despite the proximity of these sites, their sequences are quite different and until the complete and equal publication of their studies, a valid comparison and interpretation would not be possible. Although these sites are described under the title of Anatolia and modern Turkey territory, they are in fact northern Levantine sites in Mediterranean zones. The situation in the mainland of Anatolia itself has remained quite an enigma for the time period of Middle to Upper Paleolithic Transition.

Caucasus

Caucasus (in this entry southern Caucasus) also presents notable insights concerning the expansion of attributed modern human cultures and the disappearance of Neanderthals ones that have useful implications for ongoing debates of Middle to Upper Paleolithic transition in Eurasia. The Middle to Upper Paleolithic pattern of cultural changes in southern Caucasus seems to be relatively abrupt in comparison to Levant. Reassessment of old excavations and new research in several sites in Georgia and Armenia, where the Middle Paleolithic lasted until 35,000 years ago, tend to demonstrate that the genuine Upper Paleolithic is without local precedent and can be intrusive to this region (Bar-Yosef et al. 2006). The main evidence for this claim on Caucasian Middle and Upper Paleolithic transitional industries come from two cave and rockshelter sites "Dzudzuana" and "Ortvale Klde" on the southwestern slopes of the Caucasus Mountains. The lithic assemblage from the earliest Upper Paleolithic at Ortvale Klde contains unidirectional blade cores, end scrapers on blades, rounded flake scrapers, burins on truncation, retouched bladelets, and backed bladelets. Beside lithic artifacts, several bone/antler points and decorated objects were discovered in Early Upper Paleolithic layers (Adler et al. 2006). Similar materials were never discovered in the underlying Late Middle Paleolithic layers, which were dominated by Levallois technology and a typical group of Middle Paleolithic scraper types (Adler et al. 2006).

In Dzudzuana Cave, the early Upper Paleolithic industry is characterized by the production of short blades and small bladelets from unidirectional blade/bladelet cores. Microliths are very common and there are typical burins and end scrapers on flakes and blades. The later Upper Paleolithic layer in Dzudzuana contains an industry dominated by the production of small blades and bladelets detached predominantly from carinated cores.

Apparently, there is no clear evidence at either site for interaction between Neanderthals and modern humans attributed cultures. In Ortvale Klde, the Late Middle Paleolithic sequence was overlain by a genuine early Upper Paleolithic occupation (Fig. 7). Interestingly, the lowermost Upper Paleolithic unit in Dzudzuana contains an industry similar to Upper Paleolithic layers of Ortvale Klde. At both sites, the Upper Paleolithic sequence begins at *about* 34–32 Ka BP. Similar industries were also recovered from both the northern and southern slopes of the Caucasus, for instance Mezmaiskaya Cave (Golovanova et al. 1999) dated to 35–34 Ka BP as Ortvale Klde (Adler et al. 2006) or Bondi Cave date to 31–24 ka 14 C BP (Tushabramishvili et al. 2012). To researchers, this homogeneity of Early Upper Paleolithic lithic industries across Caucasus suggests that the modern humans had more success in fast expansion across mountains in compare to Neanderthals, probably due to better communication abilities and improved equipment (Bar-Yosef et al. 2006). It is also believed that the Caucasus Mountains may have been a biogeographical and social barrier to the Neanderthals, since the Mousterian industries from the southwestern slopes are similar to the Zagros-Taurus types, while the Mousterian of the northwestern slopes of the Caucasus resembles the Eastern Micoquian.

Arabian Peninsula

The Arabian Peninsula is a geographical bridge between Africa and Eurasia, and its Pleistocene archaeological evidence is of significant interest in tracking the southern route of population expansion from Africa. Compared to Levant and

Middle East Middle to Upper Paleolithic Transitional Industries, Fig. 7 The Middle and Upper Paleolithic of Ortvale Klde and proposed correlation with Greenland Ice Cores. (After Adler et al. 2006)

other part of the Middle East, the study of Modern Human origins began relatively late in Arabian Peninsula. Given the scarcity of stratified sites and absolute dating, it is not yet possible to create a comprehensive idea of Middle to Upper Paleolithic Transition in Arabian Peninsula. However, recent research has found some archaeological affinities with North Africa and Southwest Asia, mainly based on Middle Paleolithic discoveries in coastal areas (Marks 2009; Rose et al. 2011; Delagnes et al. 2012). But the Upper Paleolithic of Arabia is less known and the current state of data has documented a long sequence of laminar technologies that date back to around MIS 4 through early MIS 1 (~75–8 ka).

Several sites, like Al-Hatab Rockshelter and Shi'bat Dihya1 inYemen, provide evidence for human occupation in southern Arabia during MIS 4 and MIS 2 (Delagnes et al. 2012). The site of Jebel Faya 1 with remains dated to MIS 5 and MIS 3 (Marks 2009) and Upper Paleolithic sites recorded in the Wadi Hadramaut are examples of Arabian Upper Paleolithic sites that were all found in marginal environments. Jebel Faya rockshelter in Sharjah Emirate is one of the a few stratified excavated Paleolithic sites that have yielded radiometric dates for Arabian Peninsula Paleolithic cultures (Marks 2009). The lithic materials are associated with three distinct archaeological layers of Jebel Faya spanning a major part of the Late Pleistocene. The preliminary results of radiometric dates indicate an age of at least 85 ka for its Middle Paleolithic assemblage (C), while later assemblages (A and B) fall in MIS 3 (Marks 2009). Typo-technologically, the lowest assemblage is characterized by small handaxes, bifacial foliates, hard hammer blades and centripetal cores, and the next upper assemblage (B) is characterized by the production of flakes from 90° cores and flat cores. There are a number of multiple platform cores as well as a few truncated faceted pieces and blade production in addition to some volumetric cores. Tools comprise sidescrapers, endscrapers, denticulates and simple retouched pieces. Later assemblage (A) is characterized by the production of small rectangular flakes from multiple platform cores. The purposeful blade production is very rare, although a few short, wide blades exist. Tools categories include burins, retouched pieces, and small number of endscrapers, sidescrapers and denticulates (Marks 2009). Apparently, the Jebel Faya 1 assemblages A and B show no obvious technological relations to any transitional industry in the Levant or Africa.

Apart from the site Faw Well, which based on its similarities to late Ahmarian of the Levant probably date back to late MIS 3, other contemporaneous sites throughout Arabia show no close affinities to either the Levant or East Africa. The

Faw Well, located east of the Asir Mountains in southern Saudi Arabia, seems to be the only convincing evidence for an Levantine Upper Paleolithic presence in Arabia (Marks 2009). The small collections from Faw Well typo-technologically resemble the later Ahmarian of the southern Levant, which date to about c. 24 and 20 ka.

At most of the sites, the blade technology is relatively different from contemporaneous Levantine sites and the absence of el Wad points and finely retouched blades and bladelets, makes it difficult to hypothesis any direct connections. While additional sites and absolute dates are vital to interpret these industries, currently the most accepted view is that they are parts of a long term, local developmental sequence of Arabian lithic industries. However, during early MIS 3, a period of increase in precipitation occurred in Arabia, which increased the possibility of demographic exchanges between Arabia and adjacent regions (Fig. 8). For instance, southern Arabian populations may have spread to the north during this time and disperse a Nubian-derived Levallois technique used in production of elongated points from bidirectional Levallois cores, one of the technological characteristics of the Middle-Upper Palaeolithic transition industries in the Levant (Rose et al. 2011).

International Perspectives

Middle East and its key location is particularly important in the studies based on the leading model of "out of Africa" or diffusion theory, which discuss the expansion of modern humans and their innovative Upper Paleolithic culture out of Africa into Eurasia, and ultimately replacing the earlier hominids. However, followers of an alternative model believe gradual local evolution from Middle Paleolithic to Upper Paleolithic played a more important role in Middle East and present some archaeological evidence in accordance with their model. But the development of research in the past two decades led to a more complex image, which attempts to adapt both local developments and interactions. The variety of the geographical and cultural contexts in which

Middle East Middle to Upper Paleolithic Transitional Industries, Fig. 8 Arabian paleoenvironmental curve indicating summed probability curve of pluvial proxy signals from MIS 5a-MIS 1 and some of the dated Upper Pleistocene archaeological sites. (After Rose and Usik 2009)

the different traditions developed, and major and minor movement of hunter gatherer groups within the regions of Middle East and into or from neighboring areas like Europe, were certainly responsible for diversified evidence of MP-UP transition in this region. Unfortunately, the current state of data is not sufficient to reconstruct the processes leading to the appearance and development of the UP in each region of Middle East. This is particularly true for the Arabian Peninsula and the major part of Turkey. But within the Levant, the transition from Middle to Upper Paleolithic defines by the Initial Upper Paleolithic, which dates back to a time range between 49 k cal BP c. and 47.5 k cal BP (Belfer-Cohen and Goring-Morris 2013). The Initial Upper Paleolithic, which seems to have its roots in local Middle Paleolithic, developed into the Ahmarian tradition or the first true Upper Paleolithic tradition of the Levant that is similar to Proto- Aurignacian and partially early Baradostian of Zagros. In the Zagros, Middle Paleolithic typo-technological elements are present in the Early Zagros Aurignacian or early Baradostian of Warwasi, but on the basis of available data, possibility of continuity from Zagros Mousterian to the Zagros Aurignacian cannot be confirmed yet. However, there is no abrupt break between the Mousterian and Zagros Aurignacian of Warwasi rockshelter, which has kept Zagros as one of the potential candidates for origin of Aurignacian (Olszewski and Dibble 2006). Also based on the Yafteh cave in Zagros, which has yielded solely Baradostian layers, there are certain technological and chronological analogies between the lower Baradostian at Yafteh and the Early Ahmarian, and then the upper Baradostian and the Levantine Aurignacian; the nature of their connections still remains open to discussion (Otte et al. 2011).

Future Directions

As mentioned previously, the degree of our information about Middle to Upper Paleolithic transitional industries or events is not the same in all regions of Middle East. In order to reach a common level of information that enables us to compare and reconstruct a more complete image of human evolution history during this period, the following points are vital to be considered:

- Need for accurate information from well-stratified sites and systematic surveys in all involving regions.
- Generating new data via modern excavation methods and technologies to reach the maximum control over the recovery of materials and accurate documentation of their context as much as possible in all regions.
- Publication of detailed typo-technological characteristics of related industries extracted from in situ materials using efficient approaches, such as reconstruction of chain operation and refitting studies.
- Reliable chronological age determinations for each industry: the systematic dating of transitional sequences in different regions.
- Adopting multidisciplinary research approaches, such as microwear analysis, geoarchaeology, micromorphology and site formation studies, raw material sourcing, additional information from zooarchaeological and palynological analysis, etc., to maximize the extraction of archaeological information and reconstruction of changes in different aspects of hunter gatherers life.
- Refinement of traditional models by establishing new progressive and flexible models to understand the process of changes and developments as they really occurred.

State of Knowledge and Current Debates

Introduction

The Middle East, the Indian Subcontinent, and Central Asia are key regions in human evolution as they are the gateway between our African homeland and the rest of the world. Understanding the early prehistory of these regions is critical to understanding both hominin dispersal patterns and the divergent evolutionary trajectories of hominins in different parts of the Old World. Here, the Middle East is defined as that part of Asia from Anatolia, the Levant, and the Sinai in the west to the Iranian plateau in the east, and from the southern shores of the Black Sea, the Caspian Sea, and the Lesser Caucasus mountains in the north to Yemen in the south. The Indian Subcontinent is defined as stretching from the eastern edge of the Iranian plateau in the west to the Chittagong hills in the east, and from the High Himalayas in the north to Sri Lanka in the south. Central Asia is defined as extending from the Caspian Sea and the Ural River in the west to the Altai, Tien Shan, and Pamir Mountains in the east, and from the Kirghiz Steppe in the north to the Iranian Plateau and the Hindu Kush in the south (Fig. 1). This entry is organized chronologically to reflect the fact that this region of intercontinental crossroads cannot be understood in isolation but must be viewed in terms of dispersals out of and into the neighboring regions.

The First Asians: 2–1.6 Million Years Ago

The earliest claim for hominin occupation outside Africa comes from the site of Riwat in the Siwalik Hills of the Pakistani Punjab (Fig. 2). Here, a number of stone flakes and a core were found that were argued to have been produced by human agency by the presence of clear bulbs of

percussion and multidirectional negative scar patterns (Dennell et al. 1988). The absence of intermediary forms among the natural stone conglomerate in which they were found further implies the genuine cultural nature of these lithics. Paleomagnetism and fission-track dating indicate that the artifact-bearing horizon is at least 1.9 million years old (Dennell et al. 1988).

To reach the Indian Subcontinent from Africa overland, it is necessary to go through the Middle East (Fig. 2). An early archaeological site in the Jordan Valley, a rockshelter called Erq el-Ahmar, suggests hominins might first have left Africa via a northern route through the Sinai. Here, flaked pebbles were found in deposits preliminarily dated by paleomagnetism and potassium-argon ratios to 1.75–1.95 million years ago (Ron and Levi 2001), but further work is needed to corroborate both the age and authenticity of the artifacts.

The site of Shuwayhitiyah in northern Arabia has also been suggested to be at the vanguard of a northern out-of-Africa dispersal (Whalen et al. 1989). Although no ages have been obtained for this site, typological comparison of the artifacts links it to the developed Oldowan of east Africa, with high proportions of choppers, some polyhedrons and spheroids and some crude bifaces and small tools (Whalen et al. 1989). Similar undated Oldowan-like occurrences in southern Arabia have been used to argue for an early southern dispersal out of Africa across the Bab al Mandab straits (Whalen et al. 1989). Without dating however, these early archaeological sites in Arabia must remain tentative as simple stone tool types recur throughout human history.

The fossil record for the Middle East, Central Asia, and the Indian Subcontinent is extremely sparse, so determining which species are responsible for manufacturing the various facies of the Lower Paleolithic in these regions is a matter of some conjecture. For this early period, there are however some candidates whose remains were

Middle East, Central Asia, and the Indian Subcontinent: Lower Paleolithic, Fig. 3 A selection of Oldowan artifacts from Dmanisi, (**a**) is a multiplatform core, (**b** and **c**) are unifacial cores, (**d**–**g**) are flakes. Drawings are not to scale. (After Mgeladze et al. 2010)

found at the site of Dmanisi on the northern slopes of the Lesser Caucasus (Fig. 2). Here, hominin fossils were recovered from a lakeside setting along with stone artifacts including unifacial, bifacial, multiplatform, and radial cores and small flakes (Mgeladze et al. 2010) (Fig. 3). Fauna at Dmanisi includes deer, giraffes, ostriches, gazelle, and rhinoceros (Gabunia et al. 2000), with cutmarks on a handful of bones indicating hominin butchery using stone tools. Paleomagnetism and argon-argon ratios indicate that the site was repeatedly used by hominins during the period 1.85–1.78 million years ago (Ferring et al. 2011). The earliest hominin remains at the site are of a robust mandible, while overlying this were several crania, gracile mandibles, and teeth. The variation in mandibular robusticity has led to the suggestion that the Dmanisi hominins were either markedly sexually dimorphic or that they represent two different species (Schwartz and Tattersall 2003). Phylogenetically, they appear to be a primitive form of *Homo erectus*, with small brain sizes and several affinities to *Homo habilis* (Rightmire et al. 2006). A subspecies designation of *Homo erectus georgicus* seems the simplest way to taxonomically situate these hominins on current evidence. Interestingly, it has been suggested that the Dmanisi hominins might be ancestral both to classic East Asian *Homo erectus erectus* and to the early African *Homo erectus ergaster* (Rightmire et al. 2006). The hominin finds from the island of Flores in Indonesia are interesting in this regard as they display many primitive features such as the wrist, curved clavicle, flared iliac blades, and relatively short legs, which indicates they are descended from a species more primitive than *Homo erectus erectus* (Brown 2012). It thus appears that hominins left Africa before the appearance of *Homo erectus* and that this species first arose in Asia and then migrated back into Africa.

The evidence for the earliest human occupation of Asia is sparse and doubtless the story will change with new discoveries in the coming years. At the time of writing, the most likely explanation for the evidence appears to be that an ancestor of *Homo erectus* left Africa just before 2 million years ago and that the exit route was a northern overland route through the Sinai (Fig. 2). Environmental reconstructions suggest that the eastern Sahara would have been savannah grassland and not desert at this time, so it would not

have presented a barrier to hominin range expansion (Dennell and Roebrooks 2005). Savannahs would also have extended continuously over much of Eurasia from the Middle East, through Central Asia and the western Indian Subcontinent, to northern China, in an area dubbed Savannahstan (Dennell and Roebroeks 2005). The abundance of medium to large mammals on the savannas would have presented hominins with a niche in which stone cutting tools could be used to butcher the carcasses of these mammals. The savannas may thus have acted as a dispersal corridor for early *Homo* (Dennell 2009). This hypothesis is consistent with the archaeological record for East Asia where the earliest site is a 1.66-million-year-old assemblage of simple stone tools from the Nihewan basin in northern China, an area which would have been savannah in the early Pleistocene (Zhu et al. 2004) (Fig. 2). On present evidence, the Dmanisi specimens are the most primitive forms of *Homo erectus* so it seems that Savannahstan may have been the source region both for East Asian *Homo erectus erectus* and African *Homo erectus ergaster*. The obligate terrestrial adaptations of *Homo erectus* may thus have evolved not on the African savannah but in the Savannahstan belt of Asia.

The Earlier Acheulean: 1.6–1 Million Years Ago

The Acheulean industry originates 1.76 million years ago in east Africa (Lepre et al. 2011) and is distinguished from the preceding Oldowan by the presence of large deliberately shaped bifacial cutting tools, often made on large flakes. The earliest Acheulean tools in Asia occur at the site of Attirampakkam in Tamil Nadu in South India (Pappu et al. 2011). The artifacts were buried in clays on the floodplain of the Kortallyar River and were dated by paleomagnetism and cosmogenic dating to 1.51 million years old. The artifacts are made mostly on large quartzite flakes and include the "type-fossil" artifacts of the Acheulean: hand axes (teardrop-shaped bifaces with a long cutting edge) and cleavers (bifaces with a broad unretouched bit as their tip). Attirampakkam also provides evidence for a long stratified Acheulean sequence, with the artifacts in the clay overlain by artifacts in ferruginous gravels, which are in turn overlain by artifacts in clayey silts which are transitional to the Middle Paleolithic (Pappu et al. 2011). This long sequence thus reflects the long term and possibly continuous occupation of India during the Acheulean.

Regional surveys of the Indian Acheulean, such as in the Raisen district in central India, the Kaladgi and Hunsgi-Baichbal basins in south-central India, and the Kortallyar basin in the southeast, have revealed a high density of Acheulean sites. A consistent pattern which emerges from all these surveys, and has also been documented in other parts of the world, is the association between Acheulean localities and freshwater sources. There also seems to have been a preference for semiarid environments (Pappu 1985), with very few sites known from the wetter more heavily forested parts of the country. In the Kaladgi basin, Acheulean sites are concentrated in the lower, dry, eastern parts of the Basin, as opposed to the subhumid upper reaches in the west (Pappu and Deo 1994). The niche of the Acheulean biface makers thus appears to have been tethered to the savannah biome.

A pattern evident at Acheulean sites in the Levant and India as well as elsewhere in the Acheulean world is that away from manufacturing localities, bifaces occur in high proportions and there are far fewer unretouched flakes than would be expected for the number of negative scars on the these bifaces (Goren-Inbar and Sharon 2006; Shipton 2011) (Fig. 4). This typological bias indicates that bifaces were preferentially curated and that hominins would often carry bifaces with them rather than produce and discard tools at the point of need.

Elsewhere in South India, an early Acheulean assemblage has been excavated at the site of Isampur Quarry on the edge of the Deccan Plateau in Karnataka. The Isampur Quarry artifacts are made from limestone slabs, and the site occurs on the edge of small paleochannel, the silts from which buried the artifacts (Petraglia et al. 1999). Electron spin resonance dating on a bovid tooth from this site produced an age of 1.27 million years old, although it could be as young as 730 thousand years (Petraglia 2011). Isampur

Middle East, Central Asia, and the Indian Subcontinent: Lower Paleolithic, Fig. 4 Assemblage composition by artifact type in the Hunsgi-Baichbal basin from excavated sites (Yediyapur IV, Hunsgi V, Mudnur X, Yediyapur VI) and surface collections (Hunsgi II, Gulball II, Yediyapur I and Fatehpur V)

Quarry is remarkable for a Lower Paleolithic site in two respects: the entire biface manufacturing sequence, from procurement of the raw material to the finished tool, occurs at a single site; and parts of the site are preserved with such spatial integrity that the artifacts are still in the positions that they were left by the ancient knappers (Petraglia et al. 1999). Analysis of the artifacts and experimental reproduction of implements have demonstrated that hominins produced hand axes by reducing slabs of medium thickness to leave the hand axe shape in plan (Fig. 5), while to make cleavers, they struck large flakes from thick slab cores (Shipton 2012). The consistency of this dual strategy for the production of hand axes and cleavers suggests the Acheulean industry was underpinned by robust mechanisms of social transmission, which may account for the unparalleled longevity of the industry. Giant cores weighing up to 65 kg were pried out of the bedrock (when they were even heavier) and propped up to allow for striking large flakes (Shipton 2012). Giant cores are present at numerous Acheulean sites where appropriate large clasts of stone are available (Sharon 2009). The ability to strike large flakes (over 10 cm in maximum dimension) from giant cores is one of the distinguishing features of the Acheulean over the Oldowan. Experimental evidence indicates that manipulating giant cores requires a lot of strength and is most easily achieved with two people working together (Shipton 2012). The appearance of the Acheulean may reflect new levels of individual strength among hominins as it broadly coincides with the emergence of the tall

Middle East, Central Asia, and the Indian Subcontinent: Lower Paleolithic, Fig. 5 A hand axe made on a limestone slab from Isampur Quarry. The *shaded area* denotes cortex from the original bedding plane of the slab

M

Middle East, Central Asia, and the Indian Subcontinent: Lower Paleolithic,
Fig. 6 Artifact density at Isampur Trench 1. *Red* = high density, *blue* = low density. Maximum number of artifacts = 186 per 1.33 m^2. Units are 1 m^2. Densities are based on artifacts mapped during excavations

Homo body plan. Spatial analysis of Isampur Quarry reveals distinct artifact clusters where different stages of reduction were being carried out (Shipton 2012) (Fig. 6). This suggests that hominins may have been working together with some producing large flake blanks, while others were retouching these into finished cleavers. The emergence of the Acheulean may reflect new levels of cooperation as it is approximately coeval with reduced levels of sexual dimorphism in hominins, indicating reduced male-male competition and long-term pair bonding between males and females (McHenry 1994).

The oldest Acheulean site in the Levant is 'Ubeidiya in the Jordan Valley. Faunal comparison, radiometric dates, and paleomagnetism put the 'Ubeidiya formation at around 1.4 million years old (Dennell 2009). Artifacts from 'Ubeidiya are mostly made on flint cobbles, although limestone and basalt are also used. The artifact types include bifaces, choppers, polyhedrons, and spheroids (Bar-Yosef and Goren-Inbar 1993). Layer K30 has the highest proportion of bifaces and also differs from the other paleoenvironments at the site in occurring in a stream channel context. The most common faunal remains from 'Ubediya are deer and horse with occasional examples of stone tool cut marks on both of these species (Gaudzinski 2004). Evron Quarry formed as a coastal site in the Levant dated by paleomagnetism and faunal correlation to c. 1.1 million years ago (Ron et al. 2003). Here, small artifacts were made on flint cobbles and pebbles from the nearby river.

The early Acheulean occurrences outside of Africa may represent a second dispersal event or the diffusion of an advantageous new technology. The fossils from the Middle East, Central Asia, or the Indian Subcontinent from this time period are too fragmentary to shed light on this question. The OH9 cranium from Olduvai Gorge in East Africa is dated to around 1.25 million years ago and is generally regarded as resembling East Asian *Homo erectus erectus* (Schwartz and Tattersal 2003). This suggests gene flow between Africa and Asia during the early Acheulean, so the distinction between dispersal and diffusion may be blurred during this period.

Homo erectus sensu lato first appears at about the same time as the Acheulean in East Africa, and fragmentary *H. erectus* remains were also found at 'Ubeidiya. This species is the first hominin to have a postcranial skeleton resembling our own with no arboreal adaptations, an elongate body and long legs (Bramble and Lieberman 2004). Several derived features of *Homo erectus*' postcranial morphology suggest adaptations for endurance running, including long legs relative

to body length, expanded articular surfaces in lower body joints, and expanded trunk stabilization muscle attachments (Bramble and Lieberman 2004). Endurance running, possibly as a hunting tactic, was thus an important component of the niche of *Homo erectus*. The Acheulean biface may have functioned as part of this niche because its long and durable bifacial edge, and its ergonomic design make it an ideal portable tool (Shipton 2011). This portability explains why at some Acheulean sites, particularly those next to rivers, we see very high proportions of bifaces: these artifacts were preferentially transported to repeatedly used locales where hominins could replace the water lost as sweat while running long distances (Shipton 2011).

The Middle Acheulean 1–0.6 Million Years Ago

The site of Gesher Benot Ya'aqov in the Jordan Valley is one of the most remarkable Paleolithic sites in the world, with its unusual levels of organic preservation yielding evidence for a wide variety of hominin behaviors that are either unknown or poorly documented elsewhere. The Acheulean occupation at the site lies just above the Brunhes-Matuyama boundary of 0.78 million years ago, with faunal comparison, uranium series, and electron spin resonance dating confirming that the site is at least 650 thousand years old (Goren-Inbar et al. 2000; Rink and Schwarz 2005). Gesher Benot Ya'aqov has yielded remains of several edible species of mammals including pig, cattle, deer, horse, gazelle and elephant, as well as plants such as the water chestnut, grapes, the prickly water lily, acorns, pistachios, olives, plums, and jujubes (Goren-Inbar et al. 2000). The site provides some of the earliest robust evidence for the hominin use of fire, with various other activities such as shellfish consumption, nutcracking, and flint knapping structured around hearths (Alperson-Afil et al. 2009). Some of the earliest known wooden artifacts come from Gesher Benot Ya'aqov, including a long branch under an elephant skull that has been interpreted as a lever which was used to turn the skull over and access the brains from the base (Goren-Inbar et al. 1994).

Unlike 'Ubeidiya and Evron Quarry where bifaces were generally made on flint cobbles, at Gesher Benot Ya'aqov, they were mostly made on large flakes of basalt and were then finished with marginal retouch (Saragusti and Goren-Inbar 2001) (Fig. 7). A variety of systematic prepared core techniques were used to produce these large flakes such as the Kombewa method, where large flake blanks were struck from the ventral surfaces of even larger flakes. One hypothesis is that Gesher Benot Ya'aqov is part of a wider large flake facies of the Acheulean, which is represented by pene-contemporaneous sites in Africa, southwestern Europe, the Caucasus, and India with bifaces made by marginally trimming large flakes struck from systematically prepared cores (Sharon 2009). The Gesher Benot Ya'aqov

Middle East, Central Asia, and the Indian Subcontinent: Lower Paleolithic, Fig. 7 Ventral surfaces and profiles of two basalt bifaces from Gesher Benot Ya'aqov. (After Saragusti and Goren-Inbar 2001)

assemblage has been argued to represent a second wave of dispersal of Acheulean hominins from Africa with hippopotamus remains from the site also indicative of an African connection (Saragusti and Goren-Inbar 2001). A cladistic analysis of the shape and flake scars on hand axes from 10 sites suggests there is an out-of-Africa clade that includes sites from the Levant, the Indian Subcontinent, and Europe (Lycett 2009). DNA from Late Pleistocene hominin species shows a coalescence age of 804 thousand years ago between *Homo sapiens* in Africa and Neanderthals and Denisovans in Eurasia, suggesting a dispersal event sometime after this date (Green et al. 2010).

The extent to which prepared large flakes represent a genuine cultural marker versus the extent to which they are dictated by available raw material is unresolved. At Latamne in the Orontes Valley, Syria, elongate bifaces were produced on large cobbles of flint, around 0.8 million years ago based on the microfauna species they are associated with (Mein and Besancon 1993). The site of Bizat Ruhama on the southern Levantine coastal plain is placed by paleomagnetism and thermoluminescence at 780–920 thousand years old. Here, river pebbles of flint were exploited for the manufacture of small tools, though no bifaces were produced at this site, perhaps because the raw material clasts were too small.

Two Acheulean sites from central India with bifaces made on marginally trimmed large flakes have been preliminarily placed in the Early Pleistocene on the basis of paleomagnetism: Chirki and Morgaon (Gaillard et al. 2010). At both these sites, the Kombewa technique is in evidence providing a link to the technology of Gesher Benot Ya'aqov. However at the site of Singi Talav on the edge of the Thar Desert in northwestern India, tentatively dated to the Early Pleistocene, hand axes were made on slabs of schistose quartzite (Gaillard et al. 2010). The predominance of cleavers at Morgaon and their scarcity at Singi Talav perhaps reflects a functional environmental difference. If, as has been suggested, cleavers were wood-working tools (Movius 1944), then they would be more desirable in more forested landscapes. In general, the Indian Acheulean is characterized by higher proportions of cleavers than is the case for regions further west.

Several Acheulean sites have been discovered in Arabia; however, very few have been excavated. The two most notable site complexes are the Wadi Fatimah near the Red Sea coast and Dawadmi in central Arabia. Dating of calcareous nodules at both sites produced dates of 200 thousand years (Whalen et al. 1984, 1988), which must be regarded as minimum ages as the nodules would have formed post-depostionally (Petraglia et al. 2009). The 32 localities identified along the Wadi Fatimah occur close to smaller tributary wadis and outcrops of rocks such as basalt andesite and rhyolite which were used to manufacture the artifacts (Petraglia et al. 2009). The Wadi Fatimah is one of the largest drainages into the Red Sea, and hominins may have used this as a corridor to penetrate into the interior of Arabia. The Dawadami localities occur in the center of the Arabian Peninsula in close proximity to two huge but now extinct wadi systems: the Wadi al Batin and the Wadi as Sahba (Petraglia et al. 2009). Both these wadis flow from western Arabia to the Gulf and would have provided a resource-rich corridor for hominins. The Dawadmi localities occur along an andesite dyke that was exploited for the production of large flake blanks, from which hand axes and cleavers were made. Dawadmi is particularly extraordinary, as Acheulean sites are spread over c. 10 km along the dyke, providing evidence for the intensive and widespread use of the landscape by hominins (Petraglia et al. 2009).

The Lower Paleolithic of Iran and Afghanistan is particularly poorly known, but some potentially Middle Pleistocene choppers, side-scrapers, and denticulates have been found in southwestern Iran (Biglari and Shidrang 2006), while the site of Ganj Par on the south-western shore of the Caspian Sea has yielded Acheulean hand axes and cleavers (Biglari and Shidrang 2006).

The oldest site yet known in Central Asia is Kuldara in Tajikistan, dated on the basis of loess deposition correlations with China, to between 995 and 880 thousand years ago (Ranov and Dodonov 2003). The artifacts at the site are simple cores and flakes without retouch made on various types of pebble. Simple technology at the fringes

of the Acheulean occupation world is also seen in Europe and may represent the loss of the more complex Acheulean biface technology in small pioneer groups. The Middle Pleistocene sees Asia become colder and drier, with the Savannahstan belt turning into a marginal environment which has been termed Aridistan (Dennell 2009). The loess and paleosol sequence of the basin between the Pamir range in Tajikistan and the Hindu Kush in Afghanistan provides a clear picture of hominin occupation during the wet interglacials and abandonment during the dry glacials of the Middle Pleistocene (Ranov and Dodonov 2003). Central Asia was thus at the edge of the hominin occupied world during the Middle Pleistocene. The artifacts from this loess-paleosol sequence are all simple core and flake assemblages lacking bifaces. A consistent pattern is emerging in the Lower Paleolithic of central Asia whereby biface traditions are found in the low lying areas and simple core and flake assemblages occur in the more mountainous regions (Vishnyatsky 1999).

The Late Acheulean and Transition to the Middle Paleolithic 0.6–0.13 Million Years Ago

Quantitative comparisons of the Gesher Benot Ya'aqov bifaces with those from the younger Jordan Valley site of Ma'ayan Barukh and the older site of 'Ubeidiya demonstrate chronological trends of increasing symmetry and outline regularity (Saragusti et al. 1998, 2005). In the Hunsgi-Baichbal Valley in India, it has been shown that bifaces from the older sites of Isampur Quarry, Hunsgi V, and Hunsgi VI tend to be relatively thicker and more elongate than bifaces from the younger sites of Teggihalli II and Mudnur X (Shipton 2012). These trends may reflect increasing hominin knapping skill during the Acheulean as producing thin broad tools is the most challenging aspect of bifacial knapping. It is interesting in this regard that one of the limitations of the knappers at Isampur Quarry knappers was the tendency to over hit the bifaces causing end-shock breakages in 23% of cases. At another workshop site, Ziarat Pir Shaban in Sindh, assigned to the Late Acheulean albeit on typological grounds, this problem appears to have been much less acute with only a single end-shock break reported (Biaggi et al. 1996). In the Hunsgi-Baichbal Valley, bifaces from the younger sites also tend to be smaller with higher flake scar densities and have been transported further from their raw material source (Shipton 2012). Such trends may reflect an increasing use-life length for bifaces during the Acheulean and by inference increasing planning depth on the part of Acheulean hominins.

The Late Acheulean is characterized by an increasing regionalization of artifact styles. This is particularly marked in the Levant, where the terminal Acheulean is known as the Jabrudian industry. The Jabrudian is represented at several cave sites in the Levant including Tabun, Jabrud, Zuttiyeh, Qesem, and Bezez, as well as open-air sites such as El-Khowm. The Jabrudian retains the hand axe element of the Acheulean but also incorporates new tool types such as racloirs, convergent scrapers, backed knives, and edge-nibbled blades (Dennell 2009). Not only are there new distinctive tool types but also the hand axes from the Jabrudian are distinctive, tending to be small, with cortical butts and heavily worked tips (Fig. 8). Regionally distinct industries such as the Jabrudian suggest the emergence of distinct group identities at this transition. At several Jabrudian sites, there are examples of hand axes being used as a Levallois cores with a large preferential scar on one surface struck from a facetted platform on the butt (DeBono and Goren-Inbar 2001). It appears that the transformation of the hand axe in this way is one route by which hominins arrived at Levallois technology. The dating of the Jabrudian is complex and has undergone several re-evaluations, but a reasonable consensus would have the Jabrudian beginning around 350 thousand years ago and ending around 200 thousand years ago (Dennell 2009). Zuttiyeh has produced a partial hominin cranium dated to 300 thousand years which is most likely *Homo heidelbergensis* (Schwartz and Tattersall 2003). This association between *Homo heidelbergensis* and the Late Acheulean is well documented in Europe and Africa. Although there are no dated sites which can be attributed to the Late Acheulean in Arabia, there is nonetheless a consistent

Middle East, Central Asia, and the Indian Subcontinent: Lower Paleolithic, Fig. 8 Jabrudian hand axe from the Azraq Oasis in Jordan. (After Copeland and Hours 1989)

pattern of assemblages with small thin hand axes associated with the use of the Levallois technique and the absence of other heavy duty tools such as polyhedrons, picks, and choppers (Petraglia et al. 2009).

In India, the Acheulean to Middle Paleolithic transition is documented at several sites including the 16R Dune in the Thar Desert, Bhimbetka and Patpara in central India, and Lakhmapur in the south. The transition appears to have been a gradual one in India with no apparent population replacement (James and Petraglia 2009). At all of these locations, the transitional assemblages are characterized by small bifaces, greater proportions of small flake tools in comparison to bifaces, and the use of the Levallois technique to produce those small tools (e.g., Haslam et al. 2011). The transitional assemblage from Patpara has been dated by optically stimulated luminescence to 131 thousand years ago (Haslam et al. 2011), while that from the 16R Dune is dated by thermoluminescence and uranium-thorium to 160–130 thousand years ago (Misra 1989). A hominin calvarium from Hathnora in the Narmada valley is dated by electron spin resonance to 165–80 thousand years old (Patnaik et al. 2009). A cladistic analysis of this specimen has assigned to it a sister clade of *H. sapiens* and Neanderthals, descended from *H. heidelbergensis* (Cameron et al. 2004). The exact taxonomic designation for this species is as yet undetermined and will have to await new fossil discoveries for it to be properly situated. Given the temporal and spatial proximity of the Hathnora find to the site of Patpara, it seems the population it represents was responsible for manufacturing the transitional industry there (Haslam et al. 2011).

The abandonment of bifaces and the shift toward small flake tools are commonly thought to be related to the origins of hafting technology. In terms of hominin cognition, the Middle Paleolithic is perhaps the culmination of the trends of increasing knapping skill and planning seen in the Acheulean with generic bifaces abandoned in favor of more task-specific small tools, made using the difficult to master Levallois technique. The transition appears to have had slightly different character in the two regions of western Asia where it is well documented: the Levant and India, and also appears to have occurred slightly later in the latter. We should therefore regard the transitions as being autochthonous processes, but given the similar end points, the possibility of interaction between the regions should not be ruled out. Genetics shows that the west Eurasian Neanderthals and east Eurasian Denisovans have a coalescence age of 640 thousand years ago (Reich et al. 2011), suggesting they had divergent histories from sometime after this date. This may be attributed to the cooler, more arid climate of the Middle Pleistocene which would have made parts of the Middle East and Central Asia uninhabitable

during glacial periods, thereby temporarily splitting Eurasian hominin populations.

In Kyrgyzstan, there is an enormous cave site called Sel'ungur where 7-m-deep excavations revealed five archaeological horizons separated by sterile deposits (Islamov 1990). A uranium-thorium date on a travertine capping the uppermost cultural layer produced a date of 126 thousand years (Vishnyatsky 1999). Although the assemblages are described as Acheulean, there are very few bifaces present. Sel'ugnur thus confirms the patterns of the Central Asian Lower Paleolithic that hominin occupation was intermittent and biface technology was scarce in the mountains. Interestingly, the site has also yielded 10 hominin teeth and a fragment of an infant's humerus which are classified as Neanderthal, a hominin ancestral to Neanderthals (Islamov 1990). Central Asia thus has affinities with hominin populations to the west in the Middle Pleistocene and may have been the route via which the *Homo heidelbergensis* population represented by the Dali cranium in China (Rightmire 2001) reached the Far East.

Acheulean sites of varying ages have been discovered on a river terrace sequence in the Gaziantep region of southern Anatolia (Minzoni-Deroche and Sanlaville 1988). In central Anatolia, surveys have revealed Acheulean sites around the obsidian source of Golludag. Excavations at one such site, Kalatepe Deresi 3, have yielded Acheulean biface technology based on the production of large flakes (Kuhn et al. 2009). The excavators draw comparisons with the Tabelbella-Tachengit method of large flake production known from North Africa. The bedrock at the base of the sequence is no older than 1.3 million years, while an overlying Middle Paleolithic layer has been dated to 160 thousand years ago. In southwestern Anatolia, the cave of Karain E has provided a 12-m Pleistocene sequence going back at least 400 thousand years (Otte et al. 1998). Five phases of Lower Paleolithic occupation have been identified in the lower part of the sequence, each separated by periods of abandonment. The artifacts are dominated by short thick flakes with side scrapers dominating the retouched pieces (Otte et al. 1998). Bifaces are notably absent, a pattern which extends up into southeastern Europe. Western Anatolia may represent another frontier for the Acheulean where Lower Paleolithic occupation is intermittent and small pioneer populations either lost Acheulean technology or chose to abandon it in the mountainous terrain. A similar pattern occurs in the Caucasus Mountains where Acheulean bifaces are relatively abundant in the Lesser Caucasus in the south but become scarce in the Great Caucasus in the north (Lyubin and Belyaeva 2006). A series of caves excavated in the Caucasus, Azych, Kudaro I and II, Cona, and Treugol'naya, show intermittent and ephemeral human occupation at high altitudes with cave bear dominating the fauna (Doronichev and Golovanova 2003). The caves were occupied between 620 and 195 thousand years ago, and hand axes are rare at these sites, except in the case of Cona where nearly half the artifacts are hand axes, but they appear to have been made on nonlocal material and carried some distance to the site.

Conclusion

The Lower Paleolithic is a long and enigmatic period in human history, and we have precious little evidence from these vast regions of western Asia. Nonetheless, several distinct patterns are discernible. The first thing to note is that the most primitive forms of *Homo erectus* are in fact Asian, suggesting that this species with its long legs and obligate terrestrialism may in fact have evolved on the Savannahstan belt of Asia rather than the smaller east African savannah. The niche of *H. erectus* relied heavily on endurance running and technologically assisted butchery, as revealed by cutmarked bone at early *H. erectus* sites like Dmanisi. It is tempting to link these two features and infer *H. erectus* pursued large animals. This niche appears to have culminated in an adaptive package of the long-limbed body of classic *H. erectus* and the long portable cutting edge provided by Acheulean bifaces. Bifaces were clearly highly curated items judging by their over-representation at many Acheulean sites, suggesting they may have been carried on the

long runs of *H. erectus*. Sites which were repeatedly used during the Acheulean resulting in the accumulation of bifaces are usually found close to sources of freshwater. This may reflect the need of *H. erectus* to replace the water lost through sweating after long runs. Evidence from Gesher Benot Ya'aqov indicates that c. 700 thousand years ago hominins were exploiting a variety of hunted and gathered plant and animal resources and consuming these at a repeatedly used location. Such behaviors may have far greater antiquity, and it is only due to the remarkable preservation conditions at Gesher Benot Ya'aqov that we have good evidence for them at that time.

The question of multiple dispersals within the Acheulean is as yet unresolved and will have to wait for the discovery of more fossil evidence and more cladistic analyses of Acheulean artifacts. There is considerable heterogeneity in the Lower Paleolithic record of the three regions described here. In the Indian Subcontinent and the Levant, there are numerous sites, and the dates span vast time periods suggesting continuous occupation. These regions were to some extent sheltered from the cooler and drier climate in the Middle Pleistocene which made other parts of western Asia less habitable. The relatively lower density of Acheulean sites in Arabia probably reflects the fact that this region was abandoned by hominins during drier climatic phases. A clear pattern which has emerged is that at the edge of the Acheulean world in the mountainous regions of western Anatolia, the Great Caucasus and eastern Central Asia occupation is intermittent, with probable abandonment during cold periods, and bifaces are either absent or rare. This behavioral pattern may reflect either the loss of complex technology due to the paucity of experts in small pioneer populations or an adaptation to mountainous environments where perhaps bifaces were less useful. The former explanation seems more likely given the presence of Acheulean bifaces in other mountainous regions such as central and eastern Anatolia, the Lesser Caucasus, and Nepal. The absence of Acheulean bifaces in the areas beyond these border regions, Eastern Europe, Siberia, and the Far East, indicates that once this technology was lost, it was not readopted when hominins moved into new low-lying areas. Comparisons of bifaces reveal important chronological trends in the long record of the Asian Acheulean, with bifaces becoming thinner over time, as well as on average smaller and with higher flake scar densities. During the Acheulean period, hominin brain size increases from c. 800 cc in *Homo erectus* to 1300 cc in *Homo heidelbergensis*, while body size remains largely the same. The chronological trends observed in Acheulean bifaces might be attributed to the evolving hominin brain with skill and planning capacity increasing during the Acheulean. The trend of increasing planning resulted in more smaller task-specific tools; these were produced using the multistage and highly skilled Levallois technique and were then often hafted, involving further stages of creating a binding agent and attaching the stone to a wooden shaft. The proliferation of such tools eventually led to the abandonment of Acheulean bifaces and the end of the Lower Paleolithic.

Middle East, Historical Archaeology of

Alasdair Brooks
The Grand Egyptian Museum (GEM) Project, Hill International, Giza, Egypt

Introduction

While not a traditional focus of research in the Middle East, historical archaeology has a growing presence in the region. Themes explored by colleagues interested in the post-1500 archaeological record encompass not just the topics of globalization and colonialism relevant to historical archaeology around the world but also topics specific to local cultural and historical postmedieval developments. The body of relevant work has grown to

the extent that both general overviews (Brooks and Young 2016) and detailed regional case studies deliberately designed to build Middle Eastern research agendas (Young 2019) are now available for the subject. Enough work has now taken place that the specific studies cited in this outline should be considered broadly representative rather than an attempt to be comprehensive. While the historical archaeology of the Middle East remains a subject of specialized interest, it also addresses themes of global relevance.

Definition

"Historical archaeology," in the New World sense of "the archaeology of the modern world," is a particularly problematic terms in the Middle East, where the history of literate cultures stretches back past 3000 BC in Egypt and Mesopotamia. The cognate European term "postmedieval archaeology" has also failed to gain traction. In much of the region, all archaeology postdating the founding of Islam in the seventh century is instead conceptualized as Islamic archaeology, with the post-1500 period broadly coinciding with the late Islamic period (Brooks and Young 2016: 22, 24). The term "Middle East" is also potentially problematic in global context since it presupposes a European definition of where a "middle" lies. The term is nonetheless so widely used to define a specific geographical region bounded by the Arabian Peninsula, Iran, Turkey, and Egypt that it would be counterproductive to seek an alternative (acknowledging that this excludes North African and Central Asian nations with strong historical and cultural links to the "core" Middle East). "BC" and "AD" are used throughout for dates. This is by far the most common local convention across the region as a whole when using the Western calendar in heritage contexts (with the exception of Israel), and "BCE" and "CE" use precisely the same core dating assumptions, albeit with different terminology.

The diversity of ethnic groups and religions historically represented in the region is often underestimated. Even allowing for the dominance of Islam across the Middle East as a whole, Christianity and Judaism have both had a strong historical presence in the region, as have demographically smaller but often historically significant still-extant religious groups such as Zoroastrians, Mandaeans, Yazidis, Samaritans, Druze, and Baha'is. And Islam is by no means a monolithic block, with the divisions between Sunni, Shia, and Ibadis crucial to an understanding of the Middle East's sociocultural and political development. Calling the subject of the present discussion, a "late Islamic historical archaeology of the Middle East" may be somewhat cumbersome, but it does allow for bridging the gap between the New World and Middle Eastern considerations of the topic while both stressing continuity with the regional past and acknowledging the transformations brought about during the increasingly globalized modern world.

Historical Background

Though there are important regional variations [see the relevant region-specific articles], historical archaeology has often focused on the impact of the postmedieval expansion of European territorial and economic colonialism, and the archaeological evidence for such topics as cultural contact, population movements, and enslavement. These themes are certainly relevant to a late Islamic historical archaeology of the Middle East. Direct European postmedieval colonial engagement with the region is temporally bounded by the Portuguese capture of Hormuz Island off the coast of Iran in 1507 and the end of the last British protectorates in the Persian Gulf in 1971. France, the Dutch East India Company, post-1870 Imperial Germany, and other European states and entities also had varying degrees of engagement with the Middle East across the post-1500 period.

However, a focus on European colonialism would risk obscuring important archaeological themes that are more specific to the post-1500 Middle East. Among these are local cultural continuity and the dominant role of the Ottoman and Persian empires across most of this period. The use of the term "Islamic archaeology" to

encompass the archaeology of the seventh century to the postmedieval period conceptually stresses continuity, even while its division into "early," "middle," and "late" acknowledges important shifts across time (see Milwright 2010 for an overview of Islamic archaeology). The multi-ethnic post-Timurid Persian (1501–1979) and Ottoman (c.1300–1923) empires together controlled most (though never quite all) of the post-medieval Middle East into the twentieth century, and a consideration of their impact is naturally key to an understanding of the archaeology of the region. It is also necessary to stress that these imperial states were economically and militarily superior to European states for the early part of this period. The Ottomans besieged Vienna as late as 1683, while Persia reached the peak of its power under Shah Abbas (1588–1629). It was only in the early eighteenth century that Europe definitively eclipsed the economic and military power of the Middle Eastern empires; as such, with the notable exception of sixteenth-century Portuguese forts, European colonial engagement with the region was primarily economic rather than territorial for much of this period. Only in the aftermath of the First World War would European states briefly assert territorial control over significant parts of the region. The sociopolitical context of the late Islamic historical archaeology of the Middle East is therefore quite distinct from New World historical archaeology.

Key Issues/Current Debates

While they only arose in the early fourteenth and early sixteenth centuries, respectively, the Ottoman and Safavid states were simply the latest in a long historical line of imperial states in the Middle East, and archaeology is dominated by research agendas focusing on earlier periods. This raises important questions about archaeological significance, whether decisions to ignore (or sometimes destroy) postmedieval and late Islamic archaeology are deliberate or stem from a simple lack of awareness and what constitutes "heritage" in a Middle Eastern context.

It is very difficult to make generalizations across such a complex region, but focusing initially on territories that once formed part of the Ottoman Empire, Dikkaya (2017) has convincingly argued that the lack of a developed Turkish archaeology of the Ottoman period (c.1300–1923) can be attributed to a deliberate ideological decision in the early years of the new republican government. Following the collapse of the Ottoman state at the end of the First World War, the Turkish republic lost most of the non-ethnic Turkish population to a variety of factors (including territorial losses for the Arabs, population exchanges for the Greeks, and genocide for the Armenians). The new republic therefore rejected an Ottoman Empire that was simultaneously predominantly Islamic in self-presentation and ethnically heterogeneous in practice as an appropriate ideological predecessor of the new secular and mono-ethnic state. Instead archaeology and heritage narrowly focused on much earlier periods, such as the Hittite Empire of Anatolia (c.1600–c.1200 BC), even though Turkish states only took control of the Anatolian plateau in the eleventh century AD. The majority of the historical archaeology of the Ottoman Empire has therefore taken place outside the borders of the modern Turkish republic.

In Israel, Uzi Baram has been particularly active in studying and promoting the archaeology of the Ottoman past both in national context (e.g., Baram 2007) and more broadly across the region (Baram and Carroll 2000). Studies have also taken place on the politically fraught events of 1948 and their aftermath, including from Palestinian perspectives that might not otherwise be a focus of archaeology in either Israel or Palestine (e.g., Nairouz 2008). However, in a situation mirroring the development of archaeological studies following the establishment of the Turkish republic just 25 years earlier, conscious decisions were made following the establishment of the State of Israel to ideologically root the new nation's archaeological past in the more distant past in order to stress the antiquity of Jewish settlement in the territory of the new nation. Studies in modern Palestine and Israel by external scholars have likewise often tended to focus on Biblical archaeology. The

motivations between external and internal scholars may not always align, but the outcome – likely bolstered by a broader public perception about how old a site should be to be the target of "proper" archaeology – has again been a focus on earlier periods rather than the four centuries of Ottoman rule in historical Palestine (Brooks and Young 2016: 26).

Iran and Egypt are very different nations, but historical archaeology faces significant – and not dissimilar – challenges in both countries. In what are recurring themes across the region, the extraordinary richness of the archaeological record, the ideological and iconographic prominence given to ancient civilizations (in this case Ancient Egypt and Achaemenid Persia, respectively), and a tourist market focus on these same civilizations all lead to an archaeological research focus on earlier periods. Given these factors, it is wholly understandable that financially strapped academic programs and hard-pressed local authorities focus archaeological resources on the latter. Nonetheless, work relevant to historical archaeology is still taking place. In Egypt, the Red Sea coast has been a particular focus of historical archaeology, with Le Quesne's work at the Ottoman and Napoleonic Quseir fort on the Egyptian Red Sea coast seeking to learn more about the origins and development of the fort and its role in the late Ottoman Red Sea world, among other objectives (Le Quesne 2007). Ward's work on the eighteenth-century Sadana Island shipwreck, undertaken in cooperation with the Egyptian Supreme Council of Antiquities, sought to place its cargo, particularly the 1000 nearly complete examples of Chinese Porcelain, within the context of international late Ottoman trade networks (Ward 2004). In Iran, Papoli-Yazdi's Bam Ethnoarchaeology Project, set up in the aftermath of the devastating 2003 Bam earthquake, explored the public and private lives of families and individuals via a synthesis of excavation, oral histories, and material culture analysis (Papoli-Yazdi 2010: 35–44). Young (2019) has also used building analysis, excavation, artifact analysis, and ethnographic interviews to study the nineteenth- and twentieth-century communities in Iran, comparing the latter with similar communities in Oman in order to develop research agendas specifically oriented toward developing historical archaeology across the Middle East.

Moving focus to the Arabian Peninsula, the countries of the latter are, in their current form, largely nineteenth- or even twentieth-century colonial or postcolonial foundations. Even Oman and Yemen, which can both claim roots in much earlier states (notwithstanding varying degrees of direct and indirect British colonial engagement), only achieved their current boundaries and political status in the period following the Second World War. In many of these countries, the majority of population groups were either nomadic Bedu or coastal pearl fishers well into the last century, and the twentieth-century discovery of petroleum and natural gas reserves wholly transformed the region's economy, societies, and geopolitical significance. These factors have led to extensive debates on what even constitutes heritage in Gulf countries and the extent to which heritage should be protected. In Saudi Arabia, these factors intertwine with the dominant Wahhabi interpretation of Islam. While Saudi authorities rightly note the need to improve the infrastructure for the millions of pilgrims to Mecca and Medina, particularly during the annual Haj, the impact has also been to destroy sites suffering from the taint of idolatry (as defined by Wahhabis). By some counts, 95% of the buildings dating to the Ottoman and earlier periods have been destroyed in the last 20 years (Page 2014: 324). This destruction encompasses both significant sites from the early Islamic period, such as the houses of the Prophet Mohammed and his first wife Khadija, as well as late Islamic sites such as the Ottoman-era Ajyad Fortress, the latter torn down (despite protests from the Turkish government) to make way for the Abraj Al Bait, the vast hotel and clock tower complex that now overlooks Mecca's Grand Mosque. Yet Saudi Arabia is also home to five cultural UNESCO World Heritage sites, two of which (At-Turaif District in ad-Dir'iyah and Historic Jeddah, the Gate to Makkah) are inscribed on the list for the importance of their late Islamic heritage. Heritage and archaeology are therefore not inherently incompatible with Saudi Arabia's national ideology; the

issue is the intersection of certain types of heritage and archaeology with a particular vision of Islam.

There has nonetheless been real growth in historical archaeology, including urban archaeology, on the Arabian Peninsula in the last decade. Pearl fishing, for example, was an important component of the international Persian Gulf economy for centuries (only declining with the development of cultured pearls in the opening decades of the twentieth century), has been the subject of extensive archaeological study across periods (Carter 2012), and has seen the development of two UNESCO world heritage sites focused on postmedieval pearling. The abandoned and ruined pearling town of Al Zubarah, occupied in the eighteenth and nineteenth centuries, is highly unusual in the Middle East for having gained UNESCO world heritage status specifically for its postmedieval archaeological significance. It has been the subject of extensive (if intermittent) archaeological work since the 1950s, with more recent work in the twenty-first century seeking to understand the significance of pearling in the development of modern Gulf economics and politics (e.g., Richter et al. 2011). In Bahrain, several nineteenth and twentieth-century sites in Muharraq City have been inscribed on the UNESCO list as "Pearling, Testimony of an Island Economy," though the site has been occupied for longer; the current fort on the site dates to the nineteenth century, but the earliest fort was a Portuguese structure built in the 1630s. While the Muharraq sites were not inscribed on the UNESCO list as archaeological sites, mitigation fieldwork has taken place prior to the development on more than one occasion in what is now the designated area, often with a strong focus on the nineteenth and early twentieth-century archaeological evidence (e.g., Carter et al. 2011). Among the artifacts recovered from the site were nineteenth- and early twentieth-century British and Dutch refined white-bodied earthenwares and Chinese porcelain, often collectively referred to as "late trade wares" in the Gulf region. These ceramics have been studied from sites in Bahrain, Qatar, and the United Arab Emirates in recent years, with analysis often seeking to link European and East Asian "trade ceramics" with broader European and Asian trade networks (Brooks and Young 2016: 29–30) and therefore providing a material means to link local late Islamic archaeology on such themes as pearl fishing with an international historical archaeology of trade and globalization.

International Perspectives

While still a nascent subdiscipline, the late Islamic historical archaeology of the Middle East has considerable international potential. This is not simply a matter of the inscribing of archaeological sites with important late Islamic components on the UNESCO World Heritage list. The archaeological record of the Middle East can also make an important contribution to an understanding of the globalized modern world. That the Middle East was integrated into the emerging global trade networks of the postmedieval world, as both an export and an import market, is amply demonstrated by archaeological studies of pearl fishing and European and Asian ceramics. The Middle Eastern material culture record can therefore make an important contribution to these standard themes within historical archaeology. At the same time, Islam is a world religion of global significance, and understanding the material record of the late Islamic period can play an important role in helping to understand the region's important role in modern geopolitics. But there are challenges in presenting this potentially important archaeological record to a broader international audience. The first comes in convincing historical archaeologists – traditionally dominated by North Atlantic scholars (though with increasingly important contributions from Europe, Latin America, Australasia, and South Africa) – to engage with a region outside of their traditional geographical spheres of interest. The second comes in convincing Middle Eastern archaeologists that historical archaeology should be proactively studied and can make a key contribution toward understanding regional heritage. Important strides have been made in addressing both challenges, but much also remains to be done.

Future Directions

For all the potential for a globally integrated late Islamic historical archaeology of the Middle East, there is considerable scope for expanding the awareness of a regional shared body of work, and its relevance to international historical archaeology. At present, historical archaeology in the region tends to be focused on individual countries, with occasional links between countries in specific subregions. Fraught geopolitics can also be a factor, with regional political tensions often hampering collaboration and cooperation. The sometimes difficult relationship between nationalist and religious ideologies and the inevitable impact this has on the conceptualization of heritage in modern Middle Eastern states will also remain a challenge. These factors give Young's work in Oman and Iran, as cited above, particular significance as it engages in transnational comparisons across the Persian Gulf and seeks to set out an internationally aware regional research framework for historical archaeology. Yet there is also a key need to "demonstrate the relevance of historical archaeology to local archaeologists, heritage professionals and communities, and the ways in which archaeology can support heritage developments" (Brooks and Young 2016: 29).

Future work will also likely pay attention to postmedieval diversity in the region. The extent of religious diversity within the Middle East, notwithstanding the dominant role of Islam, has already been noted in the "definitions" section of the present discussion. A similar observation could be made on ethnic diversity. While Arabs, Turks, and Persians have been politically and often culturally dominant in the Middle East, other groups such as (but by no means limited to) Armenians, Greeks, and Kurds have also played an important role in the postmedieval Middle East. There are also groups where the link between ethnicity and religion is highly important in defining cultural identity, as with the historical and modern Jewish communities of the region. Even within the dominant ethnic groups, there are important cultural subgroups that inform heritage interpretation, with the Bedu past forming an important part of identity formation and heritage conceptualization in modern Qatar (Exell and Rico 2013: 277). Economic and class diversity can also interface with these ethno-religious examples. Future historical archaeology research in the region will likely explicitly address this diversity within all its richness, explicitly acknowledging that modern states founded on particular forms of postmedieval nationalism are not necessarily representative of the region's past.

A regional sense of continuity through time has been a recurring theme in this discussion and will likely continue to form a key part of regional research agendas, and trade is likely to form a key theme. Trade through time has not been ignored by past work. For example, a 2002 conference at the British Museum on the archaeology of trade in the Red Sea looked at this topic holistically across periods, from Pharaonic Egypt through to the late Islamic Period, with contributions in the published proceedings looking at such late Islamic-period issues as Arab perceptions of the arrival of the Portuguese, commercial exchanges between the African and Arabian coasts in the sixteenth and seventeenth centuries, and goods from an eighteenth-century shipwreck (Lunde and Porter 2004). As historical archaeologists based in other parts of the world engage with the Middle East, seeking to merge local research agendas with international agendas drawing on themes of postmedieval globalization, the extent to which postmedieval Middle Eastern trade networks with East Africa, Europe, the Indian subcontinent, and East Asia were built on existing long-standing trade patterns which evolved to encompass European economic expansion will likely form a growing field of study and an important point of comparison and contrast with New World historical archaeologies.

M

Middle East: Epipaleolithic

Deborah I. Olszewski
Department of Anthropology and Penn Museum, University of Pennsylvania, Philadelphia, PA, USA

Introduction

The Epipalaeolithic period represents a time when everyone in the world was a hunter-gatherer. But, in the Middle East, these groups were the last of the hunter-gatherers because behavioral choices they made and subsistence strategies they undertook over the course of several millennia led to one of the key economic transitions in prehistory – the origins of food production (the origins of agriculture), including the domestication of cereal grasses and herd animals such as sheep and goats.

Definition

As a term, the Epipalaeolithic is used primarily in the Middle East to describe hunter-gatherer groups who lived in the interval from about 25,000 to 11,600 calendar years ago (Fig. 1). This temporal period represents the end of the Pleistocene epoch, which was characterized by a series of global cooling and drying events that resulted in glaciations and glacial retreats in northern latitudes. In the Levant (the region incorporating parts of modern Syria, Lebanon, Jordan, and Israel), behavioral decisions regarding subsistence strategies ultimately led to the origins of food production economies, while in the Zagros (the mountainous region incorporating parts of modern Iraq and Iran), economic strategies of hunter-gatherers may have led to the domestication of goats. The 14,000-year or so duration of the Epipalaeolithic in the Middle East is characterized by a variety of named "cultures" (discussed below), some of which were archaeologically contemporary, while others represent changes in material culture and behaviors over time.

One of the hallmark features of the Epipalaeolithic is the manufacture and use of very small stone tools called microliths; these usually are less than 3 cm long and 1 cm wide and can be as small as just 2–3 mm (Fig. 2). Epipalaeolithic microliths have backing retouch, which usually means small removals along one lateral edge that are steep or abrupt (90° when compared to the exterior and interior sides of the tool). Backing is a method to blunt an edge so that the tool can be inserted into a wooden or bone handle. Backing retouch thus distinguishes Epipalaeolithic microliths from those of the Upper Paleolithic period which have very light (fine) retouch. Microliths are essentially the prehistoric equivalent of interchangeable parts. That is, by creating composite tools which consist of a handle with many microliths inserted, for example, as barbs along an arrow shaft or as elements of

Middle East: Epipaleolithic, Fig. 1 Map showing Middle Eastern areas and Epipalaeolithic sites mentioned

(**a**–**h**, **m**: drawn by Bradley M. Evans; **i**–**l**: drawn by Deborah I. Olszewski)

a knife blade, damage to any one piece can be easily repaired by removing the broken microlith and inserting a new one, rather than replacing the entire tool. In addition to a variety of other chipped stone tools, Epipalaeolithic groups also used ground stone to lesser or greater degrees. These grinding implements may have been for creating pigments in some cases but in others were undoubtedly for processing food resources such as wild cereals.

As hunter-gatherers, the majority of Middle Eastern Epipalaeolithic groups were quite mobile, moving frequently from one base camp to another. There are, however, several important exceptions, particularly during the Late Epipalaeolithic period (see below), when some parts of the Middle Eastern region were characterized by the development of small settlements where hunter-gatherers lived year-round or nearly so. These contexts and the types of cultural materials present in them have long intrigued archaeologists, especially with respect to how or if subsistence strategies undertaken by these Late Epipalaeolithic peoples may have contributed to the development of food production economies.

It should be noted that the Epipalaeolithic label also is occasionally used in other parts of the Old World, particularly for parts of Western Europe and North Africa. In the case of Western Europe, Epipalaeolithic is a marker for hunter-gatherer groups who were immediately after the Upper Paleolithic period as opposed to those of later periods. For example, the Azilian is Epipalaeolithic, while later hunter-gatherer groups such as the Sauveterrian and Tardenoisian are called Mesolithic. This distinction is in part a reflection of the large-scale habitat changes that occurred at the end of the Pleistocene "Ice Ages," when open grassland landscapes were gradually reforested as climate became warmer and wetter. Thus, the Western European Epipalaeolithic is associated with the very end of the Pleistocene and more open terrain, while Mesolithic groups lived in a heavily forested European landscape. For North Africa, the use of the term Epipalaeolithic reflects research traditions. Thus, the Iberomaurusian Epipalaeolithic groups (found in modern Morocco, Tunisia, and Libya) were named by French researchers who applied terminology familiar to them from European and Middle Eastern contexts. Other researchers prefer to use the term Later Stone Age for the Iberomaurusian and other similar groups, as this terminology, which represents the British research

tradition, is used throughout most of the African continent.

The Levantine Middle East

During the late Pleistocene, one of the important ecological distinctions was the primarily Mediterranean forest and open parkland habitats of the western Levant in contrast to the steppe and desert habitats of much of the eastern and southwestern Levant (see Fig. 1). Additionally, the eastern Levant was characterized by a series of Pleistocene lakes and marshes which provided favorable locales in an otherwise relatively cool and dry environment. The late Pleistocene also witnessed the Last Glacial Maximum (ca. 22,000–19,000 calendar years ago), a particularly cold and dry period during which Early Epipalaeolithic groups are found, followed by warmer and wetter conditions during the Middle Epipalaeolithic, which culminated in a climatic optimum during the early part of the Late Epipalaeolithic. This was followed by a brief return to much cooler and drier conditions during the Younger Dryas (ca. 12,600–11,600 calendar years ago), just prior to the beginning of the Holocene epoch, which is much wetter and warmer and which saw the advent of Neolithic societies.

Early Epipalaeolithic: Nebekian and Kebaran

The Early Epipalaeolithic occurs between about 25,000 and 19,000 calendar years ago. Two major complexes of hunter-gatherer groups have been identified; these are the Nebekian and the Kebaran (Table 1). For the most part, Kebaran hunter-gatherers were situated in the Mediterranean forest habitat of the western Levant, while Nebekian groups were found in the steppe/desert of the eastern Levant, although there are important exceptions to this pattern, particularly in the Azraq Basin region of Jordan. The stone artifact assemblages of the Nebekian and Kebaran are distinguished primarily on the basis of different forms of microliths and the fact that Nebekian groups use the microburin technique (making a notch in a bladelet [small blade] and snapping it at that place) to break bladelets into segments which can then be selected for backing into microlith tools. Most microliths of the Early Epipalaeolithic are very narrow (ca. 2 mm to 3 mm wide) nongeometric forms (see Fig. 2).

Examples of Kebaran sites include Ohalo II, Wadi Hammeh 26, and Kharaneh IV (Phase B); examples of Nebekian sites are Uwaynid 14 and 18, KPS-75 (Fig. 3), and Wadi Madamagh, while ‘Ayn Qasiyya has both Kebaran and Nebekian occupations (Nadel 2004; Olszewski 2008: 56–60; Richter 2011). Most Nebekian and Kebaran sites are small, representing high mobility, but there are exceptions. Of these, Ohalo II, situated on the shore of Lake Galilee, has extraordinary preservation of organic materials (plant remains) because of submersion by lake waters. Hunter-gatherers here constructed brush shelters; ate a wide variety of plant foods (including wild barley, acorns, and wild grass seeds), as well as fish and gazelle; and probably lived at Ohalo II year-round (Nadel 2004). In the Azraq Basin, quite large sites such as Kharaneh IV appear to represent aggregation locales where several hunter-gatherer groups came together at periodic

Middle East: Epipaleolithic, Table 1 Middle Eastern Epipalaeolithic archaeological cultures

Calendar years BP	Phase	Levant[a]		Zagros
15,000–11,600	Late Epipalaeolithic	Final Natufian Late Natufian Early Natufian	Harifian Late Ramonian	Zarzian
19,000–15,000	Middle Epipalaeolithic	 Geometric Kebaran	Early Ramonian Mushabian Hamran	Zarzian
25,000–19,000	Early Epipalaeolithic	Nizzanan Kebaran Nebekian	Qalkhan	Zarzian

intervals for various social purposes, for example, perhaps to exchange mates or exotic materials such as sea shells from the Mediterranean and Red Seas (Richter et al. 2011).

Middle Epipalaeolithic: Geometric Kebaran

In the interval from about 19,000 to 15,000 calendar years ago, Levantine hunter-gatherer groups are classified as Geometric Kebaran (see Table 1). During this period, worldwide climate began to improve, with wetter and warmer conditions compared to the Early Epipalaeolithic. Like their predecessors, most Geometric Kebaran groups were highly mobile and continued to make microliths, which included trapezes and triangles; some groups used microburin technique, while others did not. The microliths of this period are considerably wider, ranging from 5 mm to 9 mm (see Fig. 2).

Examples of sites include Neve David, Jebel Hamra (Layers A and B), Kharaneh IV (Phase D), ‘Uyun al-Hammam, and Wadi Mataha (Goring-Morris and Belfer-Cohen 1998: 77–79; Olszewski 2008: 56–60; Maher et al. 2011). Sites such as Kharaneh IV (Fig. 4) continue to be aggregation locales, suggesting long-lived traditions of cultural knowledge about place. Several important social behaviors that presage developments in the Late Epipalaeolithic are apparent at some sites. ‘Uyun al-Hammam, for example, is the earliest cemetery known in the Middle East and contains eight burials with a total of 11 individuals. A variety of grave goods (such as bone and chipped and ground stone tools) are present, but what is especially interesting is the practice of removal of human skulls (which became very common in the later Neolithic period) and the burial of a red fox skull with one of the humans. This suggests strong ties between humans and animals and may be a ritual bond that helped lead to the later domestication of several animals such as dogs, sheep, goats, and cattle.

Late Epipalaeolithic: Natufian

The Natufian is the widely recognized complex of Levantine hunter-gatherers from about 15,000 to 11,600 calendar years ago. It is divided into several phases – early, late, and final – which represent in part quite different climatic conditions and behavioral adaptations. The late Pleistocene climatic optimum, a period of expansion of the Mediterranean forest ecology, characterizes the Early Natufian, while the Late and Final Natufian witness a return to much colder and drier contexts during the Younger Dryas, during which steppe and desert ecologies expanded at the expense of

Middle East: Epipaleolithic, Fig. 4 The Early and Middle Epipalaeolithic site of Kharaneh IV (within the fenced area), Azraq Basin, Jordan. (Photo by Deborah I. Olszewski)

the Mediterranean forest. Natufians used microburin technique to make microliths, with the most common geometric form being a lunate (half-moon-shaped backed piece) (see Fig. 2). Some Natufian groups were highly mobile, while others (especially during the Early Natufian) led a more settled life in small villages.

Among the many Natufian sites are ‘Ayn Mallaha, Wadi Hammeh 27, ‘Ayn al-Saratan, el-Wad, Tabaqa, Hilazon Tachtit, and Nahal Ein Gev II (Edwards 1991; Bar-Yosef 1998; Olszewski 2008: 60–62; Munro and Grosman 2010; Grosman et al. 2016). The small villages, such as ‘Ayn Mallaha and Wadi Hammeh 27, are mainly located in the Mediterranean forest region and consist of half-a-dozen or so circular stone foundation walls for dwellings. They also contain abundant evidence associated with a more settled lifestyle, such as numerous ground stone tools, art (figurines and engraved bone tools), and dense trash deposits. A number of sites have cemeteries or burials under house floors, including a young canid (possibly a dog) buried with an elderly woman at ‘Ayn Mallaha. Although many Natufian groups became much more mobile during the Late Natufian, there is evidence for elaborate rituals and people with special roles in society. At Hilazon Tachtit, for example, an elderly woman was buried with 50 tortoise shells, a golden eagle’s wing, a gazelle horn, a wild cattle tail, a leopard’s hip, and a human foot (among other things), and there is evidence for feasting rituals, perhaps in association with her burial (Grosman et al. 2008; Munro and Grosman 2010). Moreover, settlements with stone foundations for structures, such as Nahal Ein Gev II during the Late Natufian, indicate that not every Natufian group became highly mobile during the cool Younger Dryas period (Grosman et al. 2016).

The Zagros Middle East

Compared to the Levantine Middle East, the Epipalaeolithic of the Zagros region is much less well known, primarily due to historical events that have often constrained archaeological research, although recently Iranian archaeologists have been investigating sites of this period. Hunter-gatherer groups here, like their counterparts in the Levant, experienced the climatic fluctuations of the late Pleistocene, although their behavioral adaptations are less well documented and, consequently, less well understood.

Zarzian Epipalaeolithic

The main Epipalaeolithic group in the Zagros is the Zarzian, which was first described in the late 1920s. Radiocarbon dates are not available for the majority of the sites, although based on a few dates from two sites, the Zarzian likely predates about 12,000 calendar years ago (Turnbull and Reed 1974: 84). The chipped stone industry shows changes in microliths that over time parallel those of the Levant. That is, the earliest part of the Early Zarzian has many small, inversely retouched bladelets. This is followed by the appearance of scalene triangles and microburin technique and finally by lunates in combination with scalene triangles in the Late Zarzian (see Fig. 2) (Olszewski 1993). Many of the known sites are rock-shelters or caves and are small, probably short-term occupations that suggest highly mobile groups of people.

Examples of Zarzian sites include Warwasi, Palegawra, Shanidar Cave (Layer B2), Pa Sangar, Ghar-I Khar, and Zarzi (see Fig. 1). Unfortunately, there have been very few detailed studies of the cultural materials at Zarzian sites (Olszewski 2012). Exceptions include Warwasi and Palegawra. At Warwasi, the sequence of changes in microliths is well documented, but poor preservation of animal bone means that it is possible only to say that hunter-gatherers exploited onager, wild goat/sheep, and wild pig (Olszewski 1993). On the other hand, at Palegawra, while the chipped stone assemblage has not been studied in detail, the animal bone assemblage was described. It contains at least 27 onagers, 12 red deer, 10 wild sheep, 8 wild goats, 7 Persian gazelle, 3 wild boars, and 2 aurochs (extinct wild cattle) (Turnbull and Reed 1974).

Key Issues and Current Debates

The Epipalaeolithic in the Middle East has long been of interest in the context of factors and decisions leading to the eventual shift to food production economies, including animal domestication. Much of the debate on this has traditionally focused on the Natufian (Late Epipalaeolithic), not only because of the temporal proximity of these hunter-gatherers to the period in which agriculture became increasingly important but also because of the unusual archaeological signature of the Early Natufian with its small villages, abundant ground stone tools, numerous burials and associated grave goods, and sporadic plant food remains that included wild cereals (Bar-Yosef 1998; Olszewski 2010). These behaviors, in part, seem to foreshadow those of the subsequent Neolithic. However, recent archaeological research has shown that heavy investment in wild cereals occurred much earlier, at sites such as Ohalo II (Nadel 2004), which themselves appear to be year-round occupations, although with less substantially built dwellings than during the Natufian. Exactly why, after millennia of wild cereal use, people altered their strategies to the extent that cereals became domesticated after the Younger Dryas thus remains an open question that many archaeologists still research.

Similarly, the Early Natufian small villages, and aspects of social life common to them, were long thought to be the earliest such expressions in the Middle East of complex relationships between people (often seen in burial treatment) and between people and animals (Grosman et al. 2008). More recently, however, intriguing evidence for earlier examples of complex social relationships and perhaps ideology, such as the human-fox burial at ‘Uyun al-Hammam, and evidence of long distance exchange networks for sea shells from the Mediterranean and Red Seas document that these behaviors were a part of Epipalaeolithic lifeways long before the Natufian complex (Maher et al. 2011; Richter et al. 2011).

Finally, the Middle Eastern Epipalaeolithic is characterized by a large number of archaeological cultures, including but not limited to those discussed above (see Table 1). Some of the distinctions between these archaeologically named groups are due to changes over time in hunter-gatherer mobility and behavior and the resulting alterations in cultural materials that form the archaeological signature of each. Others may represent differences between adaptations to differing habitats (e.g., Mediterranean forest versus steppe/desert). Yet other distinctions between cultural assemblages may suggest social boundaries

between contemporary, yet geographically separated, hunter-gatherer groups. Continuing research on this fascinating period will undoubtedly yield additional materials allowing much finer nuancing and understanding of the last of the hunter-gatherers in the Middle East.

Middle-Range Theory in Archaeology

Sam Crooks
School of Historical and Philosophical Studies, University of Melbourne, Parkville, VIC, Australia

Introduction

Middle-range theory is an interpretive methodology influential in New Archaeology. The concept originates in the 1950s in the sociological theory of Robert K. Merton, where it is conceived as a scale of abstraction in the process of linking low-level empirical data to high-order theories about culture (Merton 1968). In archaeology, however, middle-range theory has developed a different, materialist objective, focusing on processes of site formation and the relationship between the material record and the conditions of its production (Raab and Goodyear 1984: 255–8; Tschauner 1996: 4).

By the mid-twentieth century, the traditional culture-historical archaeological approach had successfully developed sequences of artifacts and cultures and placed these within established chronological frameworks (Greene and Moore 2010). In the 1960s, rather than simply continuing to situate archaeological material within space and time, New Archaeology, also known as processual

archaeology, sought to examine its *function*, embracing a positivist materialist approach attempting to replace the implied assumptions and interpretive intuition characteristic of traditional approaches with scientifically testable interpretations of the past. Middle-range theory, as developed by Binford in the late 1970s, is the theoretical foundation upon which New Archaeology sought to achieve this scientific epistemology.

Definition

Introduced into archaeology by Lewis Binford in the late 1970s (Binford 1975, 1977, 1978, 1981, 1983; Binford and Sabloff 1982), middle-range theory recognizes the inferential nature of all archaeological interpretation and, by processes of rigorous observation of the relationship between the static archaeological record which exists in the present and the dynamic behavioral and physical conditions of the past which produced that record, attempts to establish generalizing analogies or covering laws by which hypotheses about the past may be independently tested. Middle-range theory seeks to bridge the gap between our interpretation of the past and the past itself, positing that the study of patterned behavior in the present can be formally linked with defined material signatures. On this basis, the dynamics of human behavior in the past can be reliably inferred from material traces in the archaeological record of the present, which are established as diagnostic.

Central to this approach is an analogy based on ethnoarchaeological observation. Confronted with the problem of understanding prehistoric hunter-gatherers from material traces in the archaeological record of the present, Binford undertook extensive ethnoarchaeological research on the Nunamiut Eskimos of Canada, modern-day hunter-gathers which he believed would exhibit the same adaptive behaviors of groups at similar stages of evolution in the past (Binford 1978). Binford's theory was that objective observation of the relationship between dynamic behaviors and physical conditions on the one hand and the static physical traces they produce in the present on the other could be used to establish universal generalizing analogies with which to test hypotheses about the dynamics of the past as reflected by their physical traces. Binford was seeking a "Rosetta stone" (Binford 1983: 24), a framework of inferences built upon a sound understanding of the dynamic behavioral and natural processes which form the material record and enable archaeologists to establish correlations between the material traces of the past and the behaviors which produced them (Trigger 2006: 33).

Middle-range theory is an actualistic approach based on observation of conditions as they *actually* exist in the present (Fagan and DeCorse 2005: 364). If a correlation can be drawn between aspects of behavior and material culture in the present, then the observation of such material culture in the archaeological record enables archaeologists to infer that the same behaviors were likewise present in the past (Trigger 1995: 2).

Proponents of middle-range theory employ a suite of methodological approaches to identify these causal relationships between the material and the behavioral, all of which are linked by their reliance on processes of analogy, which assumes that if objects share some similarities, they will likely share other attributes as well, allowing archaeologists to take what is known from one context (the present) to explain data from another context (the past) (Johnson 1999: 48; Fagan and DeCorse 2005: 360). Chief among these analogical approaches is ethnoarchaeology, where what is observed of living cultures in the present day is used to infer behaviors in the past. Experimental archaeology is also used to reproduce in the present conditions and processes of the past, such as replicating the manufacture and use wear of ancient stone tools to observe the processes of their production and use (Johnson 1999: 52; Fagan and DeCorse 2005: 373–5). Taphonomy, the study of how natural and cultural behaviors create the archaeological record, encompasses many of the objectives of these approaches (Johnson 1999: 57–8; Trigger 2006: 415).

Key Issues/Current Debates/Future Directions/Examples

Middle-range theory implies a neoevolutionary perspective assuming all societies past and present go through the same fundamental evolutionary stages, such that modern-day hunter-gatherers may be taken as equivalent to similar groups in the past and thus constitute a legitimate source from which to draw analogical inferences (Trigger 1986: 10; Johnson 1999: 52). Critics observe that such assumptions are uniformitarian, not only assuming a high degree of uniformity between societies but also between physical conditions past and present (Johnson 1999: 55; Trigger 2006: 416).

Like Binford, Ian Hodder also conducted ethnoarchaeological research during the 1970s and 1980s. Heavily influenced by structuralism, Hodder championed a hermeneutic contextual approach which has been influential in the development of post-processual archaeology and is often set in opposition to Binford's middle-range theory (Hodder and Hutson 2003). Hodder argues that rather than being purely functional and adaptive, material culture is meaningfully constituted, possessed of culturally specific symbolic meanings which lie beyond the reach of the kinds of cross-cultural laws advocated in middle-range theory (Hodder and Hutson 2003: 15). Thus, rather than seeking to establish independent universally applicable laws, Hodder emphasizes the internal relations within specific cultural contexts as the proper focus of archaeological interpretations of the past.

Recent reevaluation has found that post-processualist approaches do in fact assume certain generalizing principles and make use of analogy, leading to the conclusion that rather than exemplifying the contrast between processual and post-processual approaches, forms of middle-range theory are in fact common to both (Kosso 1991; Tschauner 1996).

Migration in Historical Archaeology

Nicholas P. Ames
University of Notre Dame, Notre Dame, IN, USA

Introduction

History is defined by the movements of people. From global expansion in early prehistory to the frequent engagement of individuals in international occupation in the present, people migrate (sometimes not by choice) in response to social, political, and economic needs. These processes are a continuous, global phenomenon, with 2–3% of the world's population estimated to be in migration each year (Castles et al. 2014). These movements are occurring at different social and geographic scales, ranging spatially from local to international (Friedman 2007), temporally from temporary to permanent (Sabhlok 2019), and socially from acts of individual agency to forced migrations and slavery (Gill et al. 2011).

The processes that define migrations are often systematic, rooted in social and economic historical precedent. As a result, global developments within historical periods have had significant impact on how more recent migration processes take shape. For example, rapid technological developments in transportation and communication (de Haas 2010), the politicization of "hard" national borders (Diener and Hagen 2012), and a rise in labor-intensive industries (McNeill 1984, Castles 2002) all had influence on the durations, routes, and opportunities available to European migrants during the nineteenth century. At the same time, the processes underlying migration have had an extensive impact on global society, spurring development and social change within areas of industrialization, urbanization, agricultural production, transportation technology, community and family structures, gender roles, and sociopolitical ideologies (Kearney 1986; de Haas 2010).

As the contexts facilitating migration are often local, the processes involved can differ around the world based on these local factors. A historical migration from nineteenth-century Ireland to the United States (Miller 1980), for example, would be based in different underlying motivations, have different prospective opportunities, and take different routes (with different experiences) than a migration from China to the United States during the same period (Cloud and Galenson 1987). However, within similar historical spaces, these processes can be defined to create a general interpretive framework for understanding how migrations act as part of a broader global system. As such, this entry's discussion of migration will be rooted in the historical framework from nineteenth-century Western European migration to North America.

Historical archaeology is in a valuable position to make significant differences in the study of past migrations, as well as in our understanding of the processes and historical precedence underlying global migrations observed today. The strength of archaeology's *longue durée* perspective on human change and development enables us to contextualize the conditions that arise in the present and to recognize the implications of false narratives and misguided projections about the past on how societies engage socially and politically with these issues in the future. Alongside this, historical archaeology's use of documentary evidence together with material culture has enabled researchers to provide greater representation of marginalized migrant individuals and communities by being able to both challenge dominant narratives with material evidence on falsely represented aspects of the past, or to give voice to those wholly removed from the popular aspects of history.

While there are limitations in the ways archaeology can address migration through a material lens, such as the relatively intangible nature of direct movement resulting in a reliance of proxy data, and the complexity in projecting notions of ethnic and heritage identities onto the past, archaeology has a unique toolkit for engaging with aspects of migration in the past in a meaningful and directly socially relevant way.

Definition

Migration is a process of movement by individuals within and/or between geographic spaces for the purpose of resettlement. An individual may migrate intentionally for perceived betterment of social, economic, and/or environmental conditions, or migration could be politically, economically, or physically forced onto an individual or group (Castles 2006). These movements can be temporary or permanent, forced, or intentional and occur on local, regional, and international scales.

Migration processes are shaped by the contexts in which they occur. Simultaneously, these processes impact the social, political, and spatial makeup of those same contexts (see Anthony 1990; Skeldon 2004). For example, in nineteenth-century Ireland, significant emigration stemming from ecological and economic disaster in the form of potato blight (leading to island-wide famine) contributed to rapid depopulation in much of the country (O'Grada and O'Rourke 1997). However, the remittances returned by Irish emigrants often provided the necessary funds to improve homes and invest in communities, as well as passage to be afforded by other prospective migrants (Magee and Thompson 2006). It also introduced a significant network between communities sustained through social relationships now spanning the globe that both maintained and fostered subsequent migrations along these pathways for centuries following.

And so while emigration from Ireland was spurred by the ecological, economic, and political conditions occurring during that time, the processes of migration also contributed to reshaping those same social and ecological contexts.

Despite the local nature of these spaces from which migration occurs, similarities in social and historical contexts behind migrations often result in replications of particular frameworks for the processes involved (see Burmeister 2000; Lee 1966; or a very early attempt by Ravenstein 1885).

While tangible differences due to iterations in local responses to social conditions and pressures most certainly exist within these processes, defining a general framework for understanding the types of processes that may be involved in migration enables researchers to more easily identify where those variations exist and why.

The processes outlined below focus on patterns observed among migrants from nineteenth-century Western Europe. Between 1850 and 1913, more than 40 million people emigrated from Europe to North America and Oceania (Hatton and Williamson 1994). This period, often referred to as the era of "mass migration," was spurred primarily by economic opportunity (through labor mobility) and ecological and political hardship, although this greatly depended on the specific communities involved. Studies show comparable rates of those emigrating from urban and rural areas, suggesting significant shifts from rural to urban spaces within Europe prior to emigration abroad (following the relationship between proportion and distance outlined in number four below; see also Hvidt 1975). These migrations often reflected the framework of processes outlined below. However, it should be noted that this framework is not necessarily sequential, compulsory, nor wholly inclusive of local influences:

1. The migration process generally begins with an initial awareness of the destination (particularly for migrants seeking economic opportunity or relief; an exception would be forced migrations, such as slavery). This may be through communication with earlier migrants, by interacting with transient members of society (e.g., traveling salesman, shipping company representatives, seasonal laborers, etc. [Orser 2010]), or active recruitment by the receiving community (through distributed pamphlets or promotion of jobs within those places [Curti and Birr 1950]).
2. Migration is selective. Within nineteenth-century Western Europe, the majority of emigrants were young adult males, with "only 8 percent of the immigrants entering the United States between 1868 and 1910 [being] over 40 . . . [And] males accounted

for 64 percent of all immigrants to the United States between 1851 and 1910" (Hatton and Williamson 1994: 535). This was primarily due to young men often being the most fungible member of communities and being particularly attracted to labor market conditions. However, as reasons for migration vary depending on local circumstance, there remains variation in who is migrating within a community and why. For example, despite young males making up the majority of migrants from Europe overall, there was a much more proportionate emigration of males and females coming from nineteenth-century Ireland, due to harsh ecological and political conditions occurring within the island during that time. As a result, there was greater demographic variation represented among nineteenth-century Irish emigrants to North America, compared to many other European migrant groups (Kenny 2003). In general, young and elderly are seen as the least likely to emigrate, as are individuals who are infirm or handicapped (although Wiseman and Roseman 1979 provide a counter narrative to this point). Social and economic barriers such as gendered and familial expectations and financial cost also play a significant role in shaping migrant demographics.

3. Similarly, *who* migrates is determined largely by what motivated the migration. For example, natural disaster, war, and revolution will encourage a larger and more diverse proportion of the population to migrate over a short period of time, as with the estimated four to six million individuals displaced with the dissolution of the Ottoman Empire and onset of the First World War (McKeown 2004). These movements will often be less targeted than migrations prompted by personal agency due to the immediacy of external pressures. Economic migration, on the other hand, results in a more select group moving with relatively directed intent, as with the majority young males moving from Europe to North America during the nineteenth century (Hatton and Williamson 1994). Colonization of an area may also see diverse groups of individuals from similar origins, as with nineteenth-century British imperialism in Australia, New Zealand, Canada, and South Africa (Lawrence 2003), encouraged by the dominant government to move to specific, or series of specific, locations. Enslavement and forced relocation of peoples, however, marks a migration perpetrated by forces external to the migrant's immediate self. Thus, who is taken from a community is at the discretion of those in power. Perhaps the best-known example is the African slave trade, with close to 12 million persons being taken for slavery to the New World between 1500 and 1900 (Manning 1990). Different motivators may act concurrently upon the decision-making process, further shaping the way a migrant might engage with the migration process.
4. Volume of migration is proportional to distance. Most migration occurs on a local scale over relatively short distances, with the number of migrants diminishing as the distance increases (Ravenstein 1885; see also Friedman 2007: 558, who points out, "for every European who left Europe [from 1815–1914], nine moved within it"). This has to do with factors including fulfillment of migratory intent, diminishing degrees of local knowledge and/or that knowledge becoming more specific the further one travels from an embedded place, as well as social and economic costs increasing in proportion to distance traveled. The development of transportation technologies throughout the historic period, however, had a significant impact on the volumes, distances, and speed with which migration could take place, particularly throughout Europe. The development of steamships (Feys 2013) and expansion of railway lines (Kerr 1943) during the nineteenth century enabled European migrants to reduce the amount of time it took to immigrate to North America from weeks to days and enabled more reliable access to the American interior. It also allowed more rapid communication between communities, helping to ensure opportunities and maintain networks among these growing diasporas.

5. Migration is often a multistage process. Individuals may move shorter distances before deciding to emigrate internationally, or migrate several times in succession. This is commonly seen among temporary labor migrants, such as in Ireland, where 57,651 harvesters traveled to Britain in the summer of 1841 for agricultural labor (the first recorded year of temporary labor migration between the islands) (Kerr 1943). These laborers often traveled between different regions for work according to seasonal availability.
6. Migrants tended to favor social "centers" (densely populated urban areas) when seeking employment, socialization, and/or relief (see Guinnane 1997: 224). Urban spaces are often perceived to have greater social and economic opportunities compared to rural area. The subsequent concentration of migrants in urban spaces contributes to further development of that area due to larger labor pools, thus further promoting economic and social opportunities found within those spaces. In this sense, a cyclical relationship develops where migrations beget development begets migration (and so on).
7. Migrants often maintain connections with their departed communities. These social networks can manifest in the form of frequent communication (letters, calls, word-of-mouth, etc.), visits (during temporary returns), and remittances sent back (Esteves and Khoudour-Casteras 2011). Further developments in media technology throughout the twentieth century have made the perceived distances between communities and migrants shrink considerably (Dahan and Sheffer 2001). These networks often propagated a higher likelihood of continued migration within those communities, with new migrants tracing the same paths (or close approximates) as those who migrated before due to the process's "known" nature (Delaney 2005). Overtime, these become established "routes" within the community, who often rely on information and remittances sent by previous migrants to aid in their own process of migration. Thus, past migration influences future migration (Hatton and Williamson 1994). This systematic network of movement is often described as "chain migration," whereby community members utilize primary social relationships with previous migrants in order to facilitate their own migration (MacDonald and MacDonald 1964). However, critiques of this framing argue it implies sequential linear relationships between individuals, where in actuality "ties among individuals were most frequently multidimensional" (Samuel Baily quoted in Delaney 2005: 430; see also McCarthy 2003).
8. As a result of these networks (alongside social attitudes and perceived economic class toward many different migrant groups), migrants from similar backgrounds often become concentrated within particular regions or within specific neighborhoods of receiving communities. In 1850, for example, 78% of Irish in the United States lived in the North Atlantic region of America, compared to 40% of all Americans, "and by 1880, 1.2 million of 1.8 million Irish-born lived in those same states, or 67 percent" (Doyle 2006: 225). This concentration resulted in frequent maintenance of social and cultural expressions within these community spaces. In Pittsburgh, PA, for instance, Irish immigrants from the Gaelic-speaking West so dominated the neighborhood known as "Pittsburgh Point" throughout the mid-nineteenth century that, "even in the 1880s, Gaelic remained the spoken tongue of the Point. . .. So much so that men who had worked more than 12 years could hardly make themselves understood in English" (Walsh 1981).
9. Migration is often multi-directional. It is rarely marked by singular or unidirectional movements. Individuals, particularly seasonal or temporary migrants, often move back and forth between communities to determine/follow economic or social opportunity along community networks before coming to reside more permanently in a place (including back in the communities they initially left). This type of multi-directional migration could be intentional (i.e., temporary migration) or

unintentional (where the individual intended to remain but was forced to return for various abject circumstances) and includes an estimated "one quarter of the 16 million Europeans who arrived in the United States during the early decades of the [20th] century" (Gmelch 1983: 135). The rates of return migration are different between countries of origin, depending on local conditions, intent of migrants, and the demographics of those who initially migrated from these countries. For example, in 1908 (the first year the US government began keeping records on those departing) return migration rates to Europe were "nearly 70 percent for immigrants from the Balkans, 63 percent for Greeks, 58 percent for Italians, 34 percent for Austro-Hungarians, 22 percent for Germans, and 12 percent for British" (Friedman 2007: 558). Despite having one of the largest volumes of migrants per country entering the United States during this time, Irish return migration is estimated to "[involve] only 10 percent of the population during the nineteenth century" (McCarthy 2003: 316). A small part of these low returns can be explained through the relatively equal proportion of young adult males and females emigrating from Ireland during this time. Because emigration from other countries was disproportionately male during the nineteenth century, a common reason to coordinate return migration would have been in order to marry an individual from within their own ethnic and/or social community. However, because of the high rates of both male and female migration coming from Ireland, Irish immigrants did not have issue in finding spouses from their same communities, even within America, and thus did not need to return in order to fulfill these social desires. Thus, alongside continued economic hardship, political oppression, and perceived lack of opportunities in Ireland contributed to low rates or return.

As a result of these and other processes, it is evident that migrations can have significant effect on the social, political, and economic structure of those communities involved, as well on the systems and industries through which they move.

Historical Background

The relatively young nature of historical archaeology as a professionalized subfield (see Pykles 2008 for a brief history) means that the bulk of archaeological engagement with migration has occurred primarily within the context of prehistory (Hackenbeck 2008). While historical archaeological approaches to migration are informed by these earlier bodies of research, the field has made significant methodological and theoretical strides in investigating these processes within the context of the historical past.

While migration has been an ongoing interest in modern archaeology from its onset (Van Dommelen 2014), the subject was (and occasionally continues to be) used primarily as a causal factor of explaining material and cultural changes observed within the archaeological record, rather than a topic of study in its own right (Hackenbeck 2008). Early theoretical approaches to migration studies focused on the "push-pull" relationship between "sending" and "receiving" communities, explaining movement as the result of tension between rational actors weighing options between their current conditions and prospects of a future elsewhere (Delaney 2005; Anthony 1990; Passaris 1989; Brown 1960). This reflected studies of modern migration at the time (Piché 2013). The simplicity of "push-pull" modeling, whereby migrants are either "pushed" from a place due to adverse conditions or "pulled" to a place by economic opportunity, to explain these processes more-or-less succumbed overtime to the recognized complexity of the processes in which migrants engage. Changes in theoretical framing and subsequent methodological development within the field in the late twentieth century, influenced by debates between processual, post-processual, and World Systems Theory approaches to archaeological data and questions, influenced how migration processes were addressed by researchers. It spurred a shift away from viewing migration as a wholly chaotic

event and means-to-an-end (for both the researcher and the migrant), toward one of human processes guided by relatively predictable, albeit complex, factors, and behaviors (Anthony 1990; Burmeister 2000). As a result, contemporary views on migration perceive it as embedded in multidimensional (i.e., decisions to migrate are not singular and mono focused), multi-scalar (i.e., impacting households, communities, regions, and nations alike), multi-sited (i.e., involving both sending and receiving communities, as well as those *in-between*), and highly fluid (i.e., each aspect of the process subject to local conditions) spheres of social relation (Anthony 1990).

In historical archaeology in particular, the relationship between migration, urbanism, and industrial development is often seen as inseparable. The rapid industrial developments that characterized later historic periods (particularly in nineteenth-century Western Europe and North America) depended greatly on the cheap labor provided by a continual flow of new migrants. Informational and technological advances, in turn, had significant impacts on the pace and scope of movement accessible to migrants. For example, the invention and expansion of new systems of transportation, such as railways, steamships, and mass-produced automotives, enabled migrants to travel faster, further, and cheaper than previous methods. While the development of steamships, for example, likely did not influence the volume of individuals migrating (migrants would likely have crossed regardless of the form of vessel available), it did have an influence on the route migrants took (greater availability of steamship crossings), the conditions of travel (with development of closed berth aboard ships), and the frequency of those crossings (enabling migrants to travel back and forth with greater ease) (Keeling 2006; Page 1911). Information technology, such as methods of mass printing, made knowledge about target destinations more widely available (Cohn 2000; see also Brown et al. 1977; Golant 1971; Anderson 1983 provides a more theoretically oriented discussion on this point), as seen in the role of nineteenth-century Irish-American newspapers, such as the *Boston Pilot* and the New York *Nation*, in promoting unfiltered awareness and support for Irish independence among immigrants throughout the United States and creating a "wider, global network of communication among Irish people at home and abroad" (McMahon 2009). Coupled with the increased speed of dissemination through inventions such as the telegraph, telephone, and eventual development of the internet, means of relaying information and maintaining connection between communities was much more attainable to migrants than ever before (although, as noted by Anthony 1999: 896, "social organization, trade relationships, and transportation technology [such as capacity consideration among shipping lines] [continue to] constrain some of these processes").

Field Methodology

Historical archaeology uses documentary evidence alongside material remains to investigate aspects of the past: in this case, migration.

Using material data, i.e., physical objects that are often recovered through archaeological excavation, researchers can investigate patterns of processes that may manifest within migrant spaces due to the enactment of "habitual routines" (Lightfoot et al. 1998). Material objects and their patterns of distribution can reflect movement through contextual displacement, whereby certain objects or spatial layouts are viewed as "common" in one area, but "uncommon" in another. As migrants bring with them particular understandings of how to situate themselves in a space, these "routines of habit" often manifest in private spheres, such as domestic structures (Lightfoot et al. 1998), and are identified by differentiation from surrounding spatial practices. Additional ways archaeological data can provide insight into the lives of migrants is by investigating patterns of consumption and disposal within household sites (which can indicate socioeconomic status, food preferences and/or availability, frequency of object use, etc.), identifying or sourcing object origins, further engage with modes of long-distance transport (such as

Migration in Historical Archaeology, Fig. 1 A phenomenological study of ship life during a transatlantic crossing aboard the 1917 Dutch Tall Ship *Oosterschelde.* (Photos by author)

excavation of the slave ships *Henrietta Marie*, *Fredensborg*, and *Adelaïde* [Webster 2008]) (also see Fig. 1), as well as placing migration within the framework of settlement abandonment (as with understanding conditions for departure from the deserted village of Slievemore in Co. Mayo, Ireland [McDonald 1998]).

This use of material data is often complimented by historical documentary evidence. Documentary evidence utilized by historical archaeologists includes any historical data not found in the archaeological record. This often includes written sources, such as personal records, published accounts, correspondence, and historical databases or catalogues, but can also refer to oral histories, personal narratives, photographs, and maps, among others (see Table 1 for additional examples). These documentation types can help provide contexts and associate memories with objects recovered from the archaeological record, which aid in the construction of object itineraries and understanding the role of materiality in creating places with meaning (Joyce and Gillespie 2015), in this case, by migrants.

Documentary evidence can often provide specific personal information of individuals associated with an archaeological site or object, such as names, dates, and addresses. It can provide political context through passed legislation regarding attitudes toward migrants (such as the *1917 Immigration Act* [H.R. 10384; Pub.L. 301; 39 Stat. 874], which severely restricted the number of immigrants entering the United States and barred some individuals and ethnic groups altogether), provide images of objects in use or within primary contexts, and detail purchasing habits of specific families or individuals recorded in receipt ledgers at local shops (Wall 2014). Correspondence between migrants and distant families provides evidence for persisting community links that may not be otherwise materially apparent, as well as supply personal narratives of immigrant experiences.

Migration in Historical Archaeology, Table 1 List of documentary types archaeologists often use in conducting historical research

Source	Information type	Exemplar/citation use
Birth and death records	Place and dates of birth and death; names of relatives	Lewis and Gowland (2007)
Baptismal records	Place of baptism; relatives present; religious affiliations	Cannon and Cook (2015), Arnold (1990)
Marriage records	Place and date of marriage; used in reconstructing kin networks	Bittles and Smith (1994)
Diaries/journals	Personal experiences	Mayne and Lawrence (1999), Adamson (2015)
Letters and personal/professional correspondence	Narratives of experiences; routes traveled; opinions regarding place of settlement	Moreton (2016)
Wills	Relationships and list of relatives and descendants; personal wealth and holdings at end of life; types of objects seen as having value and respective distribution amongst a community	Mayne and Lawrence (1999)
Photographs	Clothing style and quality available to the individuals, and form of presentation; objects present in the images; indications of type of relationships between those portrayed	Januarius and Teghels (2009)
"Traditional" or oral knowledges	Local narratives of community interest/memory; local perspectives on relationships and community events	Fowles (2011), McDavid (2002), Anderson (2004)
Applications for assisted emigration/personal and professional sponsorship	Personal situation of prospective migrants; types of assistance sought and locations requested; what knowledges are available within the local community, and whom they are asking for aid	Mr. Tuke's Fund for Assisted Emigration 1882–1985
Club records	Social relationships; community responsibilities; consistency of participation	Nyhan (2015)
Shop ledgers	Types and rates of goods consumed in particular neighborhoods; names or residents purchasing; debts owed and credits extended	Stobart and Bailey (2018)
City directories	Personal and business addresses; local advertisements	De Cunzo (1987)
Federal and State census records	Place of birth of individual and parents; occupation; health condition; education level; personal addresses	Gray (2011)
Ship manifests	Passenger lists; ports of departure and entry; types of items imported into local markets	Wesley (1942), Davis (1989)
Historic maps	Residential and spatial distribution information of historic communities	Sanborn Fire Insurance Maps
City development records	Personal addresses; residential information; archived narratives	Somers et al. (1973)
Newspapers	Transport schedules; passage advertisements; published letters/correspondence	Harris et al. (1989)
Shop purchasing catalogues	Period reference for material objects/consumption	Sears, Roebuck and Co. Catalogue; Oswald (1960)

As such, documentary materials often provide information otherwise unobtainable in the archaeological record about those individuals who previously occupied an excavated space. This type of documentary evidence helps researchers correlate material findings with social realities, interject notions of personhood and agency into archaeological spaces through evidence of lived

experience, and/or challenge written narratives of social status, experience, and sociopolitical engagement of individuals or groups through evidence found in the material record (SpencerWood 1987).

Because of the ephemeral nature of migration processes and human movement, it is often difficult to detect directly in the archaeological record. Documentary evidence allows archaeologists to investigate the above processes through written narratives and community records detailing the experiences and movements of individuals engaged in the process. These documents are often used to contextualize material evidence recovered from identified spaces inhabited by migrants (e.g., specific households, boarding houses, processing centers, modes of transport, densely occupied neighborhoods, etc.) (see Fig. 2).

The importance of using archaeological methods to verify or challenge narratives provided by documentary sources is also evident in contexts where documentary records are sparse, absent, or skewed toward particular social perspective (Gray 2011). Material evidence for these processes enables researchers to engage with questions and populations "largely muted in the documentary record" (Skowronek, this volume), while gaining insight into intangible aspects of lived experiences through a critical application of whatever documentary evidence may be available.

Key Issues/Current Debates

As with any evolving research endeavor, there exist some methodological and theoretical issues with the way current archaeology approaches a study of migration. Several key issues are outlined here:

1. Perhaps one of the most prominent issues regarding the study of migration from a material lens is how evidence for movement manifests (or does not) in the archaeological record. Many early to mid-nineteenth century, researchers interpreted abrupt changes in

Migration in Historical Archaeology, Fig. 2 Line of boarding houses occupied primarily by Irish and German migrants during the nineteenth century along Green Street in Clinton, Massachusetts, still in use today. (Photo by author)

product consumption, presence, or design as indicative of individuals or groups of a different cultural origin interjected into an existing system/community (e.g., see Childe 1950). Later critiques of this direct correlative interpretation of material change argued for greater complexity and agency in the ways migrants and communities display culture, identity and/or ethnicity materially, and how it may (or may not) manifest in the archaeological record (Burmeister 2016).

The intangible nature of direct movement means that, as a product of the field, all archaeological investigation into the matter is dependent on proxy data to imply movement in some way (such as the aforementioned abnormal interjections of cultural indicators) or engages with some other aspect of a migration process other than the physical act of migrating itself. However, because migration is made up of many components beyond pure physical movement, there are avenues of working around this issue while remaining embedded in an archaeological lens. Many historical archaeologists try and focus on transitional spaces, such as boarding houses and other temporary residences, with which migrants often engage during the migration process (e.g., see Orser 2011; Davies et al. 2013), or by investigating particular neighborhoods comprised of historically concentrated migrant populations (see Yamin, this volume, for an overview of urban archaeology at Five Points neighborhood in New York City, comprised largely of Irish immigrants of the mid-nineteenth century). By investigating spaces of temporary residence, experiences of travel, and areas in which migrants are heavily concentrated (essentially, those definable spaces with which migrants frequently engage), we can work to document brief slices of these material and social realities and stitch them together to manifest pieces of a larger process of migration that is otherwise defined by intangible movements. However, regardless of diligence with which we approach these questions as a field, the majority of these processes are archaeologically inaccessible, being lost in action, over space, and within time.

2. A second key issue is to what degree can archaeologists confidently assert notions of identity and ethnicity onto past populations, particularly when ascribing a material "heritage" to a site of immigrant occupation (see "▶ Social Identity in Historical Archaeology," this volume, for a more in-depth consideration of this point).

The ways that many individuals understand heritage and social affiliation today is likely different from how it would have been perceived in the past. Contemporary perceptions of "selfhood" within the global West are heavily influenced by capitalistic and individualistic political and economic structures developed in Europe from the seventeenth century onward (Moran 2014). As contemporary identities are largely a product of compounded historical social and political construction, the elements comprising modern conceptions of identities, including heritage and ethnicity, were not necessarily an aspect of social and political life in periods of the past. An understanding of identities in the past would have been comprised of different sets of social and politically conscious modes of being in the world (Friedman 1992; see Insoll's *The Archaeology of Identities* (2007) for a thorough exploration of practical and theoretical engagement with identities in archaeology).

Furthermore, researchers are situated within the social, political, and economic contexts of modern society, and so address aspects of the past through that lens. This can lead to narratives about the past projecting an anachronistic understanding of identities and heritage onto the past, or simplifying the way identities were engaged within these historic spaces.

The role of archaeology in addressing complexities of engaging with identities in the past is particularly critical regarding national heritage laws, such as the *Native American Graves Protection and Repatriation Act* (NAGPRA 1990) in the United States. NAGPRA policy requires the demonstration

of "a relationship of shared group identity which can be reasonably traced historically or prehistorically between a present day Indian Tribe or Native Hawaiian organization and an identifiable earlier group" (NAGPRA Section 2(2); 25 USC 3001) when linking "ancient human remains and objects with the appropriate descent group" (Cameron and Ortman 2017: 8). As noted by Cameron and Ortman, this process "not only forces Native Americans to project their current identity into the past, it also brings archaeology full circle, back to the nineteenth-century goal of tracing the past migrations of contemporary groups."

3. A third issue is the way migration is often viewed as "exceptional" to social norms. The tendency for archaeological research interest to be heavily influenced by contemporary social and political debates (Härke 1998) means the perspective of a topic arising out of "abnormality" to what is expected to occur within society also translates into our social and theoretical framings of the topic. However, this framing of exceptionalism toward migration processes "obscur[es] the degree to which movement is a fundamental value for many people" (Fowles 2011, summarized in Cameron and Ortman 2017: 9). For many communities, now and in the past, degrees of migration were a critical part of how society functioned within a broader social and economic space. Nineteenth-century Ireland is often described as having a "culture of emigration" in which departure from the community by young adults was an expected part of family growth, economic strategy, and social dynamic (Miller 1980). Elsewhere, Fowles (2011) describes historic Pueblo relationships to the land as "in motion," with contemporary settlements and land claims being a byproduct of contending with western perceptions of ownership and property rights. A secondary focus of the field on migrations occurring during events of "mass migration" (periods in which significant portions of a population engage in transnational movement within a relatively short time frame (Hatton and Williamson 1994), such as observed throughout Europe during the nineteenth and early twentieth centuries) neglects more regular processes of seasonal and temporary migrations, as well as the role in economic and social development of more localized intranational migrations that make up the bulk of consistent human movement throughout the past (Friedman 2007). Migration processes are often more central to the function of a community and/or broader social system than is often considered when otherwise framed as a non-normative act of social disruption. By reframing how archaeologists think about these processes of movement and social and economic relation, we can more fully incorporate migrations into our understandings of social history and contemporary social being.

Future Directions

The questions directing archaeological inquiry have always been heavily influenced by contemporary social discourses and modern politics (Burmeister 2016; Díaz-Andreu 2001; Härke 1998).

Within archaeological studies of migration, the change in focus of migration as an explanatory factor for archaeologically observed cultural change into a topic of study in its own right during the early 1990s was contextualized by a surge of political interest and national debate concerning immigration law within the United States during that time (specifically surrounding the *Immigration Act of 1990* [Pub.L. 101-649, 104 Stat. 4978], which increased the total number of immigrants allowed to enter the United States per year, and provided family-based immigration schemes and diversity lottery programs for individuals from "low admittance" or underrepresented countries in the United States). As immigration remains at the forefront of contemporary political and social debate within America and throughout Europe, some archaeologists have turned toward using archaeological methods to engage explicitly with these immediate social issues through the materialist lens (most notably De León's (2015) investigation into the materiality of migrant camps along

the US/Mexico border, and Hamilakis' (2016) look at Greek detainment centers for undocumented migrants).

By pushing the field to engage with modern migrations directly, as these researchers have done, we are able to provide both a degree of depth to perspectives on contemporary movement, as well as inform our material understandings of the conditions impacting how these processes unfold, and the actions behind the creation of material and documentary records of migration. But perhaps more importantly, it allows us, as socially conscientious researchers, to engage through publically accessible mediums on a topic of unequivocal relevance to social concerns and shows the direct impact and influence archaeological research can have on contemporary social issues and debate.

On a broader scale, the value of a historical archaeological engagement with migration is that it allows an avenue through which marginalized populations (often those engaged in migration processes) can be engaged, and a means to challenge existing stereotypes by undermining perceived historical validity to those claims. Through the persistence of material evidence, archaeologists can open up distinctions of experience by different migrants that otherwise go lost in the past. "This is an *archaeology of care*," writes Hamilakis (2016), "which valorizes and activates small and seemingly insignificant material things, as well as the more imposing material edifices. It is *archaeology as witnessing*, which objectifies neither the migrants nor the material traces but foregrounds both as subjects and agents in the world" (Hamilakis 2016: 134).

The future direction needed by historical archaeologists in pursuing an archaeology of migration is to more strongly utilize the *longue durée* that archaeology affords within contemporary debates of modern migration (Kintigh et al. 2014). As Wurst and Mrozowski (2014) put it, we should "study history backwards," taking a known (or, at least, more informed) understanding of what arose from the past, such as contemporary social and political responses to migration, and investigate the past through the lens of that awareness. "Given that we know the outcome of choices made in the past," they write, "an archaeology of the future offers the potential to ask whether those choices were well reasoned or whether alternative trajectories would have produced a different future" (Wurst and Mrozowski 2014: 221). Historical archaeology is in a position to address these issues in the field and make a significant impact on contemporary migration debates by participating vocally in an informed manner. Although we exist in history, that does not mean history is only written in stone.

Military Activity in Islamic Archaeology

Marcus Milwright
Department of History in Art, University of Victoria, Victoria, BC, Canada

Introduction

The archaeology of warfare is construed here in its widest sense. This approach is necessitated in part by the relative paucity of published archaeological work on the actual sites of battles in the Islamic world and palaeopathological studies of those killed in war. It is also very rare for armor, weapons, banners, and other related military equipment to be recovered from excavated contexts, although such items are sometimes encountered in Muslim religious buildings, palaces, and European cathedral treasuries (and many fine examples are today housed in museum collections). As a result the majority of the entry will deal with architecture and civil engineering, dimensions of warfare that might best be described as defensive rather than offensive in character. The archaeological evidence concentrates upon the regions of the Iberian Peninsula, North and East Africa, the Middle East, and Central Asia.

Definition

Problems are encountered in establishing the extent to which given monuments or artifacts were employed in warfare or other types of armed conflict. For instance, armor, banners, and weapons might perform ceremonial roles as gifts or symbols of official status and never see active use in battle. Shi'a communities commemorating of the martyrdom of Husayn, son of 'Ali ibn Abi Talib (d. 661) and grandson of the Prophet Muhammad (d. 632), at the battle of Karbala' in 681 often make use of steel banners (*'alam*) during parades and armor and weapons in the performance of traditional "passion plays" (*ta'ziya*)

M

(Allan and Gilmour 2000: 125–210, 253–81). Turning to the built environment, it is also difficult to set out hard-and-fast rules for identifying what was constructed solely or principally for military purposes. Castles (Arabic: *hisn* or *qal'a*) obviously have important functions in times of warfare, but they might also be designed with other, less militaristic needs in mind: treasury, storehouse, prison, palace, administrative headquarters, and so on. Forts garrisoned with troops were built along the major routes taken by pilgrims performing the *hajj* to the holy cities of Mecca and Medina (Petersen in Kennedy 2006: 307–17). Other types of building (notably caravanserais) were partially fortified to defend travellers and merchants from brigandage, while elite residences were sometimes given features such as curtain walls, crenellations, and towers for more symbolic or ornamental purposes. Villages and small towns across the Islamic world were also often surrounded by walls for the protection of the inhabitants.

Historical Background

Islamic approaches to warfare and to the construction of military architecture were initially reliant upon the practices of Late Antiquity. The inhabitants of the Arabian Peninsula in the early seventh century would have been familiar with a form of square or rectangular fortified compound with a single entrance and four corner towers – good examples have been excavated at Qaryat al-Faw, Mlayha, and al-Dur – that has its origins in the Roman fort (*castrum* or *quadriburgium*). Adaptations of the Roman *castrum* also appear in eastern Syria and western Iraq in this period; in common with the Umayyad "desert castles" (also *qasr*, pl. *qusur*) of the eighth century, these Late Antique structures were employed principally for residential purposes, and the fortifications were only partially functional (Genequand in Kennedy 2006: 3–25; Milwright 2010: 34–41). Properly defensive architecture was a feature of the Late Antique Middle East and North Africa, however, and it was relatively common in this period for towns and cities to be surrounded by a curtain wall with side and corner towers and strongly constructed gates. In the territories of the Roman-Byzantine Empire, these walls were usually constructed in stone, while mud-brick and rammed earth (*pisé*) are more commonly encountered on Sasanian sites (such as Veh Ardashir, Ctesiphon, and the Erk Kala at Merv). Other types of fortifications existed, for instance, the system of walls and forts (known as "Alexander's Wall") constructed by the Sasanians to defend passes around the Caspian Sea.

During the lifetime of the Prophet Muhammad, the nascent Muslim community fought first against the inhabitants of Mecca who adhered to pagan beliefs and latterly in order to unify the tribes of Arabia under Islam. The scale of early conflicts such as the battle of Badr (624) is difficult to estimate; while they may have been little more than tribal skirmishes when compared to later events, they are important in establishing within Islamic culture the concept of holy war (*jihad*) and the virtuous status of the martyr (*shahid*) killed in warfare. The Prophet attempted to expand his influence north into Syria (culminating in defeat in 629 at the battle of Mu'ta in Jordan), but it was under his successors, the four "rightly guided" (*rashidun*) caliphs between 632 and 661 and the Umayyad dynasty (661–750), that the greatest territorial expansion was to occur. These extraordinary successes were achieved largely through battles fought successfully against the armies of the empires of Byzantium, Sasanian Iran, and the Tang dynasty of China. Smaller polities such as the Nubian Kingdom and the Visigothic rulers of the Iberian Peninsula were also defeated in this phase (Kennedy 2001: 1–58).

The most obvious physical manifestation of the Arab conquests was the establishment of garrison towns (*misr*, pl. *amsar*) that include Basra (c. 635) and Kufa (638) in Iraq, Ayla (c. 650) in Jordan, Fustat in Egypt (641–42), and Qayrawan (670) in Tunisia. No conclusive physical evidence for the layout and fortifications of these seventh-century settlements has yet come to light; only Ayla preserves its rectangular plan, round corner towers, and defensive gates, these probably dating from the early eighth century (Whitcomb in

Kennedy 2006: 61–74; Walmsley 2007: 94–5). The excavated governor's palace (*dar al-imara*) at Kufa may retain some of its seventh-century plan, including substantial walls and rectangular corner towers (replaced by round towers in a later construction phase) (Creswell 1989: 10–15). In the eighth century there is also evidence for the redevelopment of existing hilltop citadels as centers of regional government; those of Samarqand in Uzbekistan and 'Amman in Jordan have both been extensively excavated (Milwright 2010: 79–80). The militaristic aspect of Umayyad public and private art is exemplified by the so-called "standing caliph" coins (in gold, silver, and copper) that on the obverse carry the image of Caliph 'Abd al-Malik (r. 685–705) holding a sword and with a whip attached to his belt. This may be compared with stucco statues of sword-bearing caliphs from the palatial residences of Qasr al-Hayr al-Gharbi (720 s) and Khirbat al-Mafjar (740 s), both of which draw upon Sasanian royal prototypes (cf. the carved reliefs in the late Sasanian monument of Taq-i Bustan in Iran). Khirbat al-Mafjar, the bathhouse known as Qusayr 'Amra (after 711), and the Abbasid residence at Humayma also preserve diverse painted and sculpted images of soldiers and mounted archers (for illustrations of some examples, see Nicolle 1995–6: II, 24–48).

The Abbasid caliphate (749–1258) brought with it far-reaching changes to all aspects of Islamic culture. The capital of the empire was shifted from Damascus to the new city of Baghdad (constructed between 762 and 766). This circular city was extensively fortified using construction techniques employed in earlier Sasanian and Parthian cities. While nothing of eighth-century Baghdad survives, the probable form of its fortifications can be glimpsed in another Abbasid city, Rafiqa (now part of modern-day Raqqa), in northern Syria, erected between 771 and about 775 (Creswell 1989: 243–8; Daiber and Becker 2004: 3–18). Palaces too could be strongly fortified, as is demonstrated by the late eighth-century complex of Ukhaydir located in the Iraqi desert west of Kufa. This imposing structure is surrounded by a rubble and mortar curtain wall 17 m in height and well equipped with defensive towers and arrow loops (Creswell 1989: 249–58).

During the rule of the early Abbasid caliphs, there was an increasing professionalization of the army, most importantly involving the purchase of Turkish military slaves (referred to as *mamluk*s). Highly skilled as mounted archers, these Turkish troops were a potent military force. They were, however, expensive to maintain and apparently often the cause of civil unrest in urban areas. The remarkable city of Samarra (occupied by the caliphs between 836 and 892), located north of Baghdad on the Tigris river, was in part a solution to the latter problem. Stretching 35 km along the east bank of the river, a dominant feature of this urban development are the so-called cantonments, repeated compounds with central courtyards that are arranged in orderly grids within and around the major palaces. Attempts have been made to estimate the changing size of the caliphal army in the Samarran period based on the construction of these cantonments across the city (Kennedy 2001: 205–208; Kennet 2001).

The rigid grid plans of the Samarran cantonments can also be seen in the Syrian city of Rafiqa, itself designed to billet troops from Khurasan. The routes north of Rafiqa led into the contested border lands (pl. *thughur*) with the Byzantine Empire. Archaeological work in this region has revealed military towns of the eighth and ninth century such as Kharrab Sayyar and Madinat al-Far (Hisn Maslama) in Syria, and early Abbasid fortresses in southern Anatolia, including those of Haruniye and Karafrenk (Edwards 1987: 143–7, 155–6; Kennedy 2001: 190–2; Meyer and Haase in Kennedy 2006: 45–60). To the west of Rafiqa, there is an unfinished site known as Hiraqla that is believed to be a monument to commemorate Caliph Harun al-Rashid's (r. 786–809) conquest of the Byzantine city of Herakleia (Daiber and Becker 2004: 137–42).

This period also saw the emergence of a new architectural form with specifically military overtones, the *ribat*. These compounds were designed to be occupied by *murabitun*, men who for a period of years dedicated their life to the defense of the borders of Muslim polities. Hundreds of

*ribat*s were apparently constructed across the Islamic world though only a few survive. Most famous are the ninth-century *ribat*s of Sousse and Monastir in Tunisia constructed by the Aghlabid dynasty (800–909). Both adopt a square plan with corner towers that is rather reminiscent of the Roman *castrum* (Creswell 1989: 286–88; Djelloul 1999: 42–51). Excavations in Spain revealed another *ribat* at Guardamar del Segura south of Alicante composed of three rows of cells surrounded by defensive wall. This evidence may indicate that there never was a standardized plan for this military-religious institution and allows for the possibility that *ribat*s with different architectural plans will be identified archaeologically in other regions of the Islamic world (Harrison 2004: 220–6).

At the end of the ninth century, there was an increasing fragmentation of the Islamic world. The new polities of the period from the ninth to the eleventh century all invested energy in the formation of armies and the construction of defensive architecture. Palatial complexes also adopted strong fortified perimeter walls, and often the elite of the army was located in close proximity to the residence of the ruler. This is seen in the case of Madinat al-Zahra' in southern Spain, constructed during the reign of the Umayyad caliph 'Abd al-Rahman III (r. 912–61). Other partially fortified palaces have been excavated at Lashkari Bazar in Afghanistan and Kilwa in East Africa. Cities too were ringed by defensive walls; the eleventh- to thirteenth-century perimeter wall of Diyarbakr in southern Turkey runs a distance of 5 km and is constructed of ashlar masonry. Equally impressive are the walls of al-Qahira (Cairo). Established by the Fatimid caliphate (909–1171) following their conquest of Egypt in 969, this new city was initially surrounded by mud-brick walls punctuated by gateways, the most important of which were Bab al-Nasr, Bab al-Futuh, and Bab Zuwayla. Between 1087 and 1092 this circuit was replaced by stone walls and imposing fortified entrances. The new Bab al-Nasr is a particularly impressive defensive structure and also important for the carved representations of kite-shaped and round shields on its two flanking towers.

Fortified citadels became a prominent feature of the urban environment of the Middle East and Central Asia from the eleventh century onward. This development can be correlated with the increasing importance of Turkish mounted soldiers in the political life of these regions. Chief among these are the Saljuqs, a group originating in the steppe lands north of the Caspian and Aral seas who migrated south in the tenth century in order to work as mercenaries for dynasties such as the Ghaznavids (r. 977–1186). The Saljuqs ruled a major land empire in the Islamic East between 1040 and 1157 (the period of the "Great Saljuqs") and were vigorous patrons of religious and military architecture. An example of the latter is the citadel known as the Shahryar Ark constructed by Sultan Sanjar (r. 1118–57) in the northeastern part of the walled city of Sultan Kala at Merv. This great city was largely destroyed and abandoned as the result of the Mongol invasions of 1221–2 (a fate which also befell Balkh, Nishapur, and other eastern Islamic walled cities).

Citadels further west in Syria, Anatolia, and Egypt were commonly constructed in masonry and have proved more durable; the Kurdish Ayyubid dynasty (1171–1250 in Egypt and 1260 in Syria) was responsible for major citadels in Cairo and Aleppo and for the renovation of the one in Damascus. A common characteristic of these fortified centers of government is that they constituted an independent urban entity within the city; aside from the space given over to military functions, ministries, and palaces, these citadels contained many of the features – congregational mosque, bathhouses, domestic architecture, and industrial installations – also found in the city itself. Somewhat smaller fortified sites made opportunistic use of existing architecture, such as the citadel at Bosra which is built around a classical theatre.

Another major factor facilitating the evolution of defensive architecture and military technology was the changing balance of power between the Islamic world and Christian Europe, most notably the *Reconquista* in Spain (until 1492) and the establishment of the Frankish states in the Middle East following the First Crusade (1096–99). The castles and other military architecture associated

with the periods of conflict have been extensively studied (see below). The shifting of borders between Christian and Muslim polities resulted in complex phases of construction, destruction, and rebuilding. Evolving techniques of siegecraft also affected castle design, with Muslim and Christian designers learning from one another – a good example of this phenomenon is the box machicolation, which occurs at about the same time in Muslim and Frankish castles in the Middle East.

The capture of Acre by the forces of the Mamluk sultanate (1250–1517) in 1291 marked the end of the Crusader presence in the Middle East (though not the end of the Crusading movement). The Mamluks were a military slave elite who had replaced the Ayyubid sultanate. Like their predecessors they invested heavily in military architecture. Many castles were extensively rebuilt in the second half of the thirteenth century including Krak des Chevaliers (Qal'at al-Husn) in Syria and Karak and Shawbak in Jordan (Faucherre 2004). The Mamluks also recognized the importance of an effective communication infrastructure, and evidence of their postal system (*barid*) remains in the way stations and dovecots constructed along the main routes through the empire. The strongly militaristic aspect of Mamluk society is also evident in their material culture, and the personal emblems (often known as blazons) of Mamluk princes (*amir*s) are a feature of ceramics made in their capital (so-called barracks ware) and of textiles, metalwork, and glass excavated in Cairo and other urban sites of the sultanate. A cache of armor, weapons, and fragments of soldiers' clothing (sometimes with blazons embroidered upon them) from the Mamluk period was found during the archaeological investigation of the citadel in Damascus (Nicolle 2011).

Incendiary technologies such as "Greek fire" (*naft*) had already been employed in earlier centuries, but this aspect of Islamic warfare was transformed by the introduction of gunpowder. In the late fifteenth and early sixteenth centuries, the Mamluk sultanate made considerable, if not always effective, use of primitive handheld firearms (arquebuses) in war. The Ottoman sultanate (late thirteenth century–1924) also embraced cannon and handheld firearms in warfare, as did other so-called Gunpowder empires, the Safavids (1501–1722) of Iran and the Mughals (1526–1828) in India. Not only did these new weapons change the character of military engagements in the field, but they also necessitated adaptations to the design of defensive architecture (see below).

In archaeological terms some of the most interesting evidence from the fifteenth to the nineteenth centuries comes from the military encounters between Islamic and Christian polities. In preparation for the two Ottoman sieges of Constantinople (1396–1402/3 and 1453), the Ottoman sultans Bayezid I (r. 1389–1402) and Mehmed II (r. 1444–6, 1451–81) constructed the fortresses of Anadolu Hisarı and Rumeli Hisarı on the Asian and European sides of the Bosphorous. The Ottomans also extensively renovated existing fortifications as part of their ongoing struggle with the Venetian Republic for control of the Aegean and eastern Mediterranean. Impressive remains of fortresses and city walls may be found in Greek ports such as Nafplio, Nafpaktos (Lepanto), and Pylos. Elsewhere there is evidence for European military presence in Islamic regions, often involving the construction or extensive renovation of fortresses and walled settlements. Three associated with Portuguese colonial expansion are Qasr al-Saghir in Morocco, Qal'at Bahrain in the Persian Gulf, and Kilwa island off the East African coast (Redman 1986; Milwright 2010: 183–86).

The economic and military superiority of Europe is readily apparent in the history and archaeology of the Islamic world from the late eighteenth century. The Middle East and North Africa were drawn into larger conflicts (such as the Napoleonic War and World War I). Islamic regions also became the subject of the colonial ambitions of European states (most importantly France, Britain, and Russia). Recent archaeological work has recovered traces of some modern military campaigns. Notable examples are the excavation of Napoleonic trenches at 'Akko (Acre) in Israel and the survey conducted of sites in southern Jordan (Ma'an and Wadi Rutm) associated with the period of the Arab Revolt (1916–1918) (Saunders and Faulkner 2010). The

latter project is particularly significant for its focus upon the changes to the landscape caused by battles and by the creation of army camps in sparsely occupied regions. Excavation of an Islamic graveyard at the ancient site of Tell Hesi also revealed the presence of trenches dug during the war which led to the creation of Israel in 1948. These trenches were constructed prior to the battles of Hirbet Mahaz in 1948 and continued to be employed until 1959 for training purposes by the Israeli army (Toombs 1985: 6–14).

Key Issues/Current Debates

Much of the recent archaeological work on Islamic warfare has focused upon castles, city walls, and other defensive structures. While castles were obviously designed to withstand attack and could also be employed for billeting troops and as arsenals, they also performed many other nonmilitary functions. Furthermore, the main motivation for the construction of castles was not always the desire to defend borders in times of conflict; Ellenblum has demonstrated that the bulk of the Frankish castles of the Kingdom of Jerusalem was erected in phases of relative peace, and many of these structures were located at a considerable distance from the borders with the neighboring Muslim polities (Ellenblum 2007: 103–86). This leads one to question both the notion that lines of castles constituted a form of border defense and whether one should apply modern conceptions of national boundaries to the porous transitional zones that existed between medieval polities. These considerations are helpful in assessing the roles performed by castles in the Islamic world. It is apparent that fortified structures often functioned as centers of local government and as the principal markets for the surrounding rural communities. For instance, in the Mamluk period the castle and town of Karak was the capital of a district (*mamlaka*) with smaller fortified structures at Hisban, Shawbak, and elsewhere functioning as secondary centers of local government with their own staff of administrators and soldiers (Milwright 2008: 78–93). These networks facilitated the exploitation of resources from the surrounding area, protected the main roads, and provided a point of mediation between nomadic groups and the state. Broadly comparable patterns of castle building can be seen in southern Spain and in other parts of the Islamic world (Zozaya 1996).

During periods of prolonged warfare, areas of land, and the castles contained within them, would often change ownership several times (affecting such things as the size and composition of the administrative and military elite occupying castles). The excavation of important urban citadels such as Damascus and Aleppo has allowed researchers to reconstruct the fluctuations in the material culture of these sites through several dynasties and over periods of centuries (Berthier and Gonnella in Kennedy 2006: 155–75). Particularly important are cases where there are changes in the confessional affiliation of the occupants, such as during the Crusades in the Middle East, the *Reconquista* on the Iberian Peninsula, and the Ottoman conquest of Greece and the Balkans. Following the Portuguese conquest of Qasr al-Saghir, almost every aspect of the Islamic town was remodelled from the civic buildings to the domestic architecture and shops. Where the Muslim inhabitants had relied upon manufactured goods from the surrounding regions of North Africa and southern Spain, the Portuguese soldiers and merchant families of the fifteenth and early sixteenth centuries imported ceramics and other media from a wider area including northern Europe and China (Redman 1986).

Less pronounced shifts in the material culture were registered in the Islamic and Portuguese occupation levels at Qal‘at Bahrain in the Persian Gulf. More significant in this context was the transformation of the fort itself; the final construction phase, dating to the late sixteenth century, has massive walls and substantial galleries designed to accommodate cannon. The adaptation of fortifications to allow for the use of artillery (and to defend against it) has been studied on other sites including the Abdullah Khan Kala in Merv and the forts built by the Ottomans to guard the route of the *hajj* through southern Syria, Jordan, and northern Arabia (Brun 2005: 619–24; Petersen 2001). Similar issues are raised by a consideration of the

reflexive relationship between siege technology and military architecture in earlier periods of Islamic history. Recent studies of Frankish and Muslim castles of the Crusader period in the Middle East have revealed the evolution of both outer defenses and inner storage and domestic areas as the result of innovations in siege techniques (Michaudel in Kennedy 2006: 106–21; Ellenblum 2007: 189–286). Sometimes the renovation of damaged sections of a castle allowed for the creation of improved towers or curtain walls. The analysis of numerous construction phases of castles can be challenging, but considerable advances have been made in this field of study using techniques such as rectified digital photography (Tonghini and Montevecchi in Kennedy 2006: 201–24).

The evolution of Islamic weapons prior to the fifteenth century is hampered by the paucity of surviving examples (Nicolle 2011). In part, this must be connected with the Muslim prohibitions upon placing grave goods within burials (this being a significant source of excavated armor and weaponry in many early medieval cultures). Presumably, most military equipment in the Islamic world was recycled when it could no longer be repaired. Our major sources on Islamic weaponry and the techniques involved in making them are textual and visual. Particularly important in this respect is the treatise *On Swords and their Kinds* (*al-suyuf wa ajnasuha*) by the philosopher, al-Kindi (d. 870) (Allan and Gilmour 2000: 56–7). Illustrations of weaponry occur on numerous portable artifacts and manuscript paintings.

Archaeology has contributed to the study of Islamic weapons, however. Two swords were recovered from the excavations in Nishapur, both probably dating to the ninth century. The more complete example has a slightly curved steel single-edged blade (i.e., for slashing rather than stabbing) with bronze fittings and the remains of a decorative wooden scabbard. The closest correlates for the Nishapur sword exist to the north and west in the Altai mountains, the Caucasus, and Russia. During the eighth and ninth centuries, the form of sword encountered in Nishapur spread west into Europe, perhaps as the result of the Avar migrations (Allan 1982: 56–8, 108–109 nos. 208–209). The type of crucible steel employed in the manufacture of the Nishapur sword matches closely the steel ingots found in excavations of a ninth- or tenth-century workshop at Merv, about 250 km to the northeast. Merv had no local deposits of iron ore, and this material was imported. This major industry was probably focused upon the production of weapons and armor for the garrisons of the city (Allan and Gilmour 2000: 50–5). Other fragments of early swords have been excavated at sites such as al-Rabadha, an important town on the road from Medina to Kufa, and the eleventh-century shipwreck at Serçe Limanı on the southwestern coast of Anatolia (Nicolle 1995–96: II, 73–76).

International Perspectives

Warfare is an aspect of human activity that is highly sensitive to technological change, and for this reason the investigation of individual regions, sites, or artifacts always needs to maintain an international perspective. Archaeology provides a means to study manufacturing practices and the distribution of materials and weapons in different phases of Islamic history. Warfare is often also associated with economic concerns (the defense of trade routes, the opening of new markets, or the desire to obtain raw materials), and this means that the material culture excavated within fortified sites can reveal the changing extent and geographical scope of mercantile activity in different occupation phases. Traders and goods often passed across the borders of warring polities; for instance, excavations in Acre (‘Akko) have revealed the intensity of the trade in Islamic luxury goods to Europe during the thirteenth century (a fact borne out in contemporary written sources). A common concern in the design of fortified sites is the storage of food and water. The provision and storage of water through such features as aqueducts and cisterns has been studied by archaeologists working on sites as diverse as Ismaili castles in Iran, Ottoman towns in Greece, and Muslim fortresses in Spain; this body of evidence invites further comparative study within and beyond the Islamic world (Milwright 2010: 90–4).

Future Directions

With the partial exception of the study of Islamic castles and other aspects of military architecture, the archaeology of Islamic warfare is a relatively undeveloped field of study. The following comments are intended to identify areas of potential study that can build upon existing published scholarship. The rapid expansion of the Islamic state in the seventh and early eighth centuries is one of the most important events in the history of Eurasia, but archaeology has made little impact upon the debate about how and why the Arab armies of conquest were so successful. To what extent was it the weakness of the polities of the early seventh century and what weight should we give to the superiority of Arab military strategy or weaponry? Did the destructive plagues of the sixth and early seventh centuries critically weaken the societies of the Mediterranean and Middle East and thus facilitate the Islamic conquests? Further synthesis of existing archaeological data will refine our picture of the economic and political life of the Middle East and North Africa prior to the Arab conquests, while excavation of battle sites or early *amsar* like Basra or Kufa could help us form a better understanding of the characteristics of the armies of the first Islamic decades. Other periods of rapid territorial expansion such as the establishment of the "Great Seljuq" sultanate, the Mongol conquests of the thirteenth century, and the campaigns of Timur between c. 1370 and 1405 would also benefit from archaeological perspectives.

In general archaeology has provided relatively little information on the human aspects of Islamic warfare, encompassing both the lives of soldiers and of civilians affected by periods of conflict. Battlefield archaeology might well provide insights into this issue. The examination of Crusader-period skeletal remains has provided intriguing data upon weapon injuries (Mitchell et al. 2006). The imposition of large numbers of foreign troops upon a given area must have left an impact upon the environment, as well as affecting the sociocultural and economic lives of the native inhabitants. The *amsar* of the seventh and eighth centuries, the Abbasid cities of Rafiqa and Samarra, and the urban citadels of the eleventh to fifteenth centuries all provide opportunities to explore these issues. The settlement of soldiers and Turkish officials within the countryside of conquered areas has been addressed in survey work in the Pylos region of the Peloponnese (and similar issues have been productively explored in relation to Frankish settlement of the Crusader Kingdom of Jerusalem), but much more work is required (Zarinebaf et al. 2005). This also opens the possibility of comparative analyses with archaeological research in non-Islamic lands, an important recent example being the study of the impact of changes to settlement practices and animal-breeding practices during the Baltic Crusades (Brown and Pluskowski 2011). Lastly, there is an urgent need to improve our understanding of naval warfare during the Islamic period. No major study exists of an Islamic military craft or of a major engagement involving an Islamic navy.

Military Personnel Training in Archaeology

Laurie W. Rush
United States Army, Fort Drum, NY, USA
US Committee of the Blue Shield, Arlington, VA, USA

Introduction and Definition

Devastation in conflict and disaster areas often extends to archaeological sites. For military personnel to respond appropriately in situations where cultural property requires protection, three

Note: This article is written in the author's personal capacity and does not reflect the policies of the US Government, the US Department of Defense, or the US Army.

components are necessary: an educated force, legal requirements for the property to be protected, and accurate maps, documentation, and information. The most comprehensive international legal instrument governing cultural property protection is the 1954 Hague Convention for the Protection of Cultural Property in the Event of Armed Conflict (1954 Hague) and its two protocols. Over 120 nations around the world are state parties to the 1954 original agreement, meaning that, in theory, these governments have committed their militaries to the principles and practices of cultural property protection. In addition, many nations have established national register lists and heritage protection laws that offer a beginning point for understanding which properties and collections require rescue or protection. For military personnel to be effective in the protection of archaeological sites, this treaty requires education for them along with a requirement to establish a force of specially trained military personnel who are competent to respond to situations involving risks to and rescue and/or recovery of cultural property.

It is important to remember that the 1954 Hague Convention emerged in response to Nazi theft and looting of cultural property from across Europe. The convention offers an inclusive definition for cultural property with archaeological remains being one component of a comprehensive list of property types. As a result, most military education programs approach education related to protection of archaeological remains as part of a more comprehensive whole. Discussion of educating the military to protect archaeology is essentially a discussion of protection of cultural property writ large.

Background: Domestic Archaeological Protection on Military Land

For departments and ministries of defense in the United States, the UK, and some European countries, responsibility for the protection of cultural property including archaeological sites falls under either environmental or civil affairs programs or both. In the United States and in the UK, there are robust domestic stewardship programs for archaeological sites and historic structures. The US Department of Defense employs hundreds of archaeologists and may, in fact, fund more archaeological survey, site evaluation, and stewardship than any other agency on the planet. Each military installation with thousands, and in some cases millions, of acres supports an archaeological program that inventories archaeological sites and provides compliance archaeology for construction projects and training events that will result in ground disturbance. These archaeologists are hired to support the military training mission and as a result have an opportunity and a responsibility to educate the personnel who are training on the lands they protect.

In addition, in the United States, compliance with the US Native American Graves Protection and Repatriation Act (NAGPRA), a series of Presidential Executive Orders, and US Department of Defense (DoD) policy requires installation archaeologists to work as advocates for indigenous people whose ancestors lived and were buried on defense landholdings. The military archaeologists establish consultation partnerships and diplomatic relationships between leaders of federally recognized tribes and military command groups ensuring indigenous access to sacred places and protection of buried remains. In addition to educating military commanders, installation archaeologists also provide introductions to archaeology found on the training lands for military personnel with a goal of reinforcing appreciation, respect, and site protection rules. In the UK, military archaeologists work closely with English Heritage, caring for scheduled monuments on military land. Salisbury Defense Estate is probably the most archaeologically intact landscape remaining in the UK, and their installation archaeologists work daily with the military trainers to insure that soldiers are informed and that training events will not adversely affect archaeological features.

Currently, in the United States, the UK, and Austria, a small group of archaeologists who work with the military are proactively developing programs that shift the approach to archaeology stewardship on military land to one where training

lands are viewed as host nations and the protected cultural sites are sacred. This realistic approach not only vastly improves compliance with site protection protocols but also offers military personnel valuable experience to develop the skills they require to be able to identify and respect ancient places and sacred features in cross-cultural landscape settings. This approach was recently codified as a recommendation in the new US Army Guidance for Cultural Resources Management (US Army 2016).

Historical Context and "Monuments Men"

There are currently two complementary approaches being implemented to establish cultural property protection capabilities within the US military. One is to educate military personnel to the point where all types of cultural property, including archaeological sites, are taken into consideration during the course of every phase of a military operation. The other is to insure that the force includes specially educated personnel who can deploy to offer expertise in situations where cultural property is at risk and requires special attention. During World War II, the United States and the UK assigned military personnel with qualifications as archaeologists, art historians, and related fields to serve as monument officers in their "MFAA," Monuments, Fine Arts, and Archives program (Nicholas 1994). The elements of success in the MFAA program offer significant lessons learned which can be applied directly to efforts to restore cultural property protection capabilities to the deploying forces of today (Rush 2012). In the United States, preservation of the cultural heritage of Europe was recognized as a priority, and a commission recommended establishment of this force to President Roosevelt. Archives of World War II include military orders signed by Generals Eisenhower and Alexander, reiterating the importance of protecting cultural property whenever possible. Eisenhower is often quoted with respect to heritage, as he issued the following order on 29 December 1943. "To: All Commanders, Today we are fighting in a country which has contributed a great deal to our cultural inheritance, a country rich in monuments which by their creation helped and now in their old age illustrate the growth of the civilization which is ours. We are bound to respect those monuments so far as war allows." Even though US Army and Marine Corps Civil Affairs (CA) and in Europe Civil Military Cooperation (CIMIC) programs still exist, their cultural property component has been small. One exception was the deployment of Major (now retired) Cori Wegener to the National Museum of Iraq after the looting in 2003.

Archaeology and the Military Since 2003

The United States and the UK

As recent conflicts have painfully illustrated, the United States, UK, and other coalition partners have deployed forces that lacked the necessary education and information required for accurate identification of and appropriate response to the cultural property they were going to encounter. To make matters worse, these deployments were into regions of great archaeological sensitivity like ancient Mesopotamia and the silk road of Afghanistan. It quickly became clear that the World War II military cultural property protection capability had been lost.

In 2004, global media attention focused on damage at Babylon by occupation of US Marines and Polish forces (MSNBC 2004). In response, a core group of military archaeologists, academics, and heritage professionals from a series of western nations have been working to re-establish cultural property protection as an institutional element of responsible military training and operations. The Archaeological Institute of America (AIA) was among the first to respond to the challenge by initiating a Soldier Lecture Program under the direction of then President of AIA, Professor Brian Rose. This program was a volunteer effort where academic archaeologists and museum professionals traveled to military installations and offered information to soldiers and marines prior to their departure for Iraq or Afghanistan (Rose 2007).

It should be noted that there is a community of archaeologists who made an ethical choice not to

participate in any form of military partnership whatsoever (Hamilakis 2003; Stone 2011). The controversy surrounding the US invasion of Iraq in 2003 certainly contributed to the understandable concern among archaeologists about what would be an appropriate role to play in terms of educating military personnel who would be deployed to and operating in the immediate vicinity of ancient Mesopotamian archaeological sites. However, as the nature of armed conflict has changed in the second decade of the twenty-first century, bringing with it deliberate destruction of archaeological properties by armed adversaries, members of the academic community have increasingly come forward to contribute expertise. Over the past 10 years or more, archaeologists have been supporting military operations in a wide range of capacities: as academic experts offering data and "reach back" expertise, as educators assisting with pre-deployment training and military education, and as consultants for preparation of military policy, doctrine, and best practices with regard to archaeological resources. The shared goal of these efforts is the protection of archaeological sites and collections in any situation where military personnel might possibly be involved.

The Soldier Lecture Program evolved into a curriculum designed for all US Army Reserve Officer Training Cadets (ROTC) that introduces the principles of cultural property protection as part of cultural awareness training with an emphasis on archaeological sites. This program has the potential to engage interested academic archaeologists who could serve as volunteer instructors. The current challenge is reaching out to military science and academic archaeology programs on US college campuses and convincing them to partner for delivery of the required cultural property component of the cadet curriculum. The US Army ROTC Cadet Command also established a Cultural Property Internship Program at Fort Drum, NY. During the course of a month, the participating cadets learn about the Army Environmental Program, participate in archaeological survey, are introduced to Native American consultation partners, and complete a project that contributes to the US Defense inventory of cultural property training and resource material.

Some installation archaeologists in the United States and the UK, with support from academic archaeologists, began to add training for deploying personnel to their domestic archaeological survey, stewardship, and cultural resource management responsibilities. Their accomplishments include development and distribution of over 150,000 decks of archaeological awareness playing cards to deploying personnel; establishment of heritage reference websites for Iraq, Afghanistan, and Egypt (http://www.cemml.colostate.edu/cultural/cptraining.html); establishment of the Military Cultural Heritage Advisory Group or the MILCHAG; establishment of heritage protection guidelines for Central Command contingency operations in a regulatory format (CENTCOM 200–2, 2008); on-site training at Saqqara Egypt for participants in the Bright Star War Games in 2009; the addition of cultural property to military engagements in Jordan and the Arabian Gulf; initiation of CPP Subject Matter Expert Engagements in US Southern Command; development of cultural property protection scenarios for field training; development of replica archaeological sites for US Army field training; guidelines for identifying archaeological sites using defense imagery; development and delivery of archaeology and heritage awareness presentations to deploying personnel including specialized curriculum for military engineers; and funding of archaeological research related to improved understanding of ancient water systems as found throughout the Middle East, South Asia, and semiarid regions of Africa. UK colleagues, in cooperation with the British Museum, have even developed field-training aides that include mobile replica museums that can be used for military training in looting scenarios.

The Smithsonian and the University of Pennsylvania Museum Cultural Heritage Center have also become proactive partners in education of military personnel and support of research that provides a better understanding of the increasingly strategic role archaeological sites are playing in the modern battlefield. The University of Pennsylvania Museum Cultural Heritage

Center and the Smithsonian joined with other research institutions to create the Conflict Culture Research Network, a consortium designed to provide a research platform for developing a far more sophisticated understanding of how and why adversaries target archaeological sites and cultural property during the course of genocidal conflict. In addition, the Smithsonian has reached out to both US Army and US Marine Corps Civil Affairs units, offering them not just an introduction to cultural property protection but also behind-the-scenes visits for military personnel to collections at the Smithsonian and the Metropolitan Museum of Art on the east coast and the Getty on the west.

Current efforts and resources available for soldier education include presentations and workshop guidance on how CPP can contribute to mission success; how to identify cultural property on the battlefield; how to create a cultural property inventory; legal requirements for CPP both United States and global; an inventory of materials that could be installed to protect archaeological sites forward like temporary fencing and geotextiles; case studies of successes and failures in cultural property protection in the military operation context; how to handle antiquities in the case of seizure for military and customs personnel; how to inventory and document antiquities, structures, and works of art at risk; how to survey a landform for archaeology prior to a military construction project or military base expansion; CPP considerations during the course of disaster response; how to create and implement a CPP inject during the course of a military exercise; and guidance for military personnel on how to work productively with nongovernmental organizations. These resources are available for use by any archaeologist who is interested in working with military personnel.

The epitome of professional military education in the United States is the war college system where active duty officers can obtain advanced degrees in a range of civilian subjects in addition to gaining specialized education pertaining to military issues. For the first time, two of the war colleges, Air University and Naval War College, are offering graduate-level courses in cultural property protection taught by qualified archaeologists, anthropologists, and military officers. Air University is even encouraging its graduate students to take on CPP challenges as thesis topics.

Austria

The Austrian military is a world leader in cultural property protection education. The Austrian Society for the Protection of Cultural Property, whose members are military personnel, has served as an advocate for CPP since the 1980s. As a result, the Austrian Ministry of Defense has defined a military occupational specialty of Cultural Property Protection Officer. These officers, who have an academic background in history, archaeology, and/or the arts in addition to their military training and capability, interact directly with military planners and responders in peacekeeping operations.

The Austrians have established the first ever master's degree program specifically focused on cultural property protection at Donau University, Krems. The Krems program, directed by an academic archaeologist who is also a military officer, is designed to not only offer a formal MA in a traditional degree program format, but it also enriches the courses with intensive "hands-on" workshops so that the students can learn practical cultural property protection skills. Interested military personnel can participate in any workshop they would find useful without having to take the entire degree program. For example, one of the Krems Summer University workshops is on how to evacuate an archaeological collection. For 1 week, degree students along with workshop participants meet in Krems for formal presentations combined with the actual evacuation of a collection from field storage to a museum. The workshop includes critical skills like object documentation, object handling and packing, and coordination with local "host nation" rescue personnel like fire brigade members. Other workshop subjects include how to identify and map cultural property on the battlefield. The Austrians are also one of the global pioneers in using actual archaeological remains located on military training lands to support CPP scenarios in military exercises. On behalf of UNESCO, the Austrians have also

offered cultural property training courses for defense professionals from all over the world.

The Italian Model

The Italians lead the world in effective military deployment capability for CPP with a militarized police force whose officers specialize in protection of archaeological sites and objects in addition to other forms of protection for art and cultural material (Rush and Benedettini 2015). Called the Carabinieri Tutela Patrimonio Culturale, or the Carabinieri Command for the Protection of Cultural Property, these policemen have established an international database for missing archaeological objects and works of art, investigate and attempt to prevent incidents of looting at archaeological sites, and have recovered thousands of objects and works of art from all over the world amounting to hundreds of millions of euros in value. Carabinieri officers deployed to Iraq in 2003 as peacekeepers where they helped Iraqi heritage professionals capture and prosecute looters of archaeological sites; recovered objects stolen from the National Museum of Iraq; established a database of additional stolen objects; did aerial surveillance of archaeological sites in Nasiriyah and Dhi Qar Provinces, enabling them to provide Iraqi provincial inspectors with detailed site map coordinates and perimeters; and reopened the provincial museum at Nasiriyah (Carabinieri 2008). The Carabinieri TPC, in cooperation with the University of Turin, even opened a virtual Museum of Iraq (http://www.virtualmuseumiraq.cnr.it/prehome.htm).

Of special importance is the Carabinieri's global approach to site guard and training programs for international policing. These programs are designed to assist police forces and military organizations around the world, emerging as effective partners for the protection of art and archaeology. More specifically, they work to establish proficiency in protection of archaeological sites, to provide a template for establishing partnerships between police and ecclesiastical agencies for protection of sacred property, and to increase prosecutorial capability for convicting looters and traffickers in stolen art and antiquities on a nation-by-nation basis. The Carabinieri demonstrated their skills in Iraq when they assisted in re-establishment of the Iraq site guard program in the early 2000s. They made the case for the core elements required to protect an archaeological site: support from the local community, viable transportation like trucks and fuel, reliable communications like radios, the ability to carry a weapon when necessary, salaries for the guards, and uniforms in order to communicate the official and respected nature of the work (Rush and Benedettini 2015). It is interesting to note that as of 2017, the Carabinieri are playing a key role in reeducation and capacity building for Iraqi police forces, including those officers who are responsible for protecting cultural property (Parrulli 2017). The Carabinieri's proactive approach to international training and assistance has been extremely productive. At a recent meeting between representatives from US Southern Command, the Honduran military, the Roman Catholic Church, and Honduran cultural organizations, the Hondurans described significant progress in protection of churches as a direct result of Carabinieri courses offered in Central America.

Academic Approaches to the Subject of the Military and CPP

A series of research programs, dissertations, and books on the subject of protection of archaeological sites in conflict zones are emerging including projects at the University of Newcastle UK, the University of Amsterdam, Colorado State University, the University of Kansas in partnership with the US Command and General Staff College, University College Dublin, Indiana University of Pennsylvania, and Deakin University, Melbourne, Australia. The right to one's heritage is now recognized as an international human right, so protection of archaeological sites and heritage is now a component of legal discussions and included in law school programs and courses at DePaul University, Tulane; the University of Sienna, Villanova; and the International Institute of Humanitarian Law, San Remo, Italy. The Institute has recently partnered with the University of Turin to also offer a master's degree in CPP,

although given the nature of the partnership, it will probably be more focused on the legal aspects of the issue as opposed to the more practical approaches offered at Krems. Many of these programs are also making an effort to reach out to military personnel to encourage them to enroll.

One of the most fascinating and exciting accomplishments in the world of academic archaeology and the military has been the creation of Operation Nightingale in the UK (British Archaeology 2012). This program has achieved outstanding success by using participation in archaeological excavations as a form of therapy for wounded personnel. Operation Nightingale now has an established track record for genuinely assisting with emotional recovery while offering soldiers the opportunity to gain confidence working side by side with civilians. Participants also graduate from the program with the skills required to work on future archaeological projects, and some soldiers even gain more specialized marketable skills like surveying and scientific illustration as they prepare to return to the civilian world. Several participants in Operation Nightingale have gone onto university to study archaeology, and many are now serving on the compliance archaeology field crews on the UK Defense Estates. There are nascent attempts to duplicate Nightingale in the United States with a recent excavation at Fort Ligonier, PA.

An additional international program that deserves recognition is the Museo-bus of Senegal. The curator of the military museum in Dakar has created a traveling opportunity for the education of African military forces on the protection of cultural property. By using a mobile educational platform, the Senegalese military can reach out to counterparts across West Africa in order to increase awareness of the importance of protecting archaeology and heritage sites especially during the course of peacekeeping operations (Diatta 2012). Officer Ismaila Diatta contributed his example as part of an International Centre for the Study of the Preservation and Restoration of Cultural Property (ICCROM) program called "First Aid for Culture in Crisis Areas." Begun in 2011, this program is designed for all who care about saving heritage and welcomes all interested students and professionals including members of the military. The program has expanded beyond ICCROM's home in Rome, and the 2016 course was hosted by the Smithsonian Institution.

Archaeology and the Military Today

It is important to note that current initiatives in military training and education for cultural property protection are mainly focused on the need to educate the entire force for effective protection of archaeological sites during all phases of a military operation. In order to convince military leaders of the importance of protecting archaeological sites and other forms of cultural property, they need a sophisticated understanding of how the ability to recognize and respond to cultural property on the battlefield will contribute to mission success. This type of comprehension means that all military personnel should have at least an introductory level of awareness concerning the heritage of any nation where they may be operating. Once an appreciation for the importance of cultural property including archaeological sites has been institutionalized across the force, it should then encourage the development and use of specialized monument officers, hopefully bringing back a form of the MFAA as known in World War II (Rush 2012).

Archaeology, Cultural Property, and Phases of Military Operations

Mapping and "No Strike Lists"

The earliest phases of a military operation, of course, involve planning. During the planning phase, mapping and identification of archaeological sites is critical. Military personnel cannot avoid or protect features in the landscape that are unknown to them. One of the most important roles an archaeologist can play in protection of archaeological sites in conflict zones is provision of information to the Ministry or Department of Defense that includes location, nature, and size of archaeological sites that are at risk. In the United States, the US Defense Intelligence

Agency (DIA) handles this information, and currently academic archaeologists working with the US Committee of the Blue Shield (USCBS) are providing data sets related to archaeological sites and collections they would like to see protected by US personnel. USCBS has an agreement with the Digital Archaeological Record (tDAR), a not-for-profit organization based at Arizona State University designed to archive archaeological data. tDAR protects and archives these restricted data sets which USCBS shares only with DIA . Once DIA has incorporated these data into the Modernized Intelligence Data Base or MIDB, the archaeological information is added to the nonlethal targeting or "no strike" lists that are issued prior to any form of military action. It is very important to note that any archaeologist who contributes sensitive site information will always retain control over with whom that information may be shared whether it is residing at tDAR, DIA, or both. Very recently, DIA established a system whereby a nonclassified version of MIDB archaeological data can be shared back with selected archaeologists for update and/or quality assurance. DIA has also begun to incorporate discussion of the importance of cultural property protection into its military education activities (Varley 2017).

Kinetic Operations

The military, generally, is operating at the very local level, and sacred and valued features in small villages and settlements are rarely noted on the kinds of inventories that would be used during the planning process or that would be included on military maps. As a result, it is important to work with soldiers on the ability to recognize indications that they are in the vicinity of or on an archaeological site in addition to the kinds of clues that people use to indicate a sacred feature. The presence of offerings, symbols of prayers, sometimes even natural features that stand out in a foreign landscape are all critical for the ability to identify and respect the cultural property of others.

During what is called the kinetic or most violent phases of conflict, the military has to be prepared for situations where adversaries use cultural property for strategic and tactical advantage. In Iraq, Saddam Hussein deliberately placed military bases in the immediate vicinity of ancient Mesopotamian cities like Ur with the hope that western forces would hesitate to attack out of concern for potential collateral damage. The challenge in cases like these is to insure that an incoming force is prepared to minimize the impact of their presence once they assume responsibility. Training for military engineers includes opportunities for them to learn site assessment and implementation of environmental baseline protocols prior to occupying, establishing, and/or expanding a base in the immediate vicinity of an important archaeological property.

Adversaries may also use cultural property like headstones or archaeological ruins as firing points or places of worship as locations for sequestering large quantities of weapons or explosives. Military forces need to be prepared for these eventualities, and the training includes the skills required for what is called proportionate response. For example, well-trained military personnel will attempt to minimize return fire when being fired upon from a cemetery or archaeological ruins in order to do as little damage as possible. This type of training also includes a thorough introduction to the legal requirements for cultural property protection in situations like these. In the United States, a decision to attack a historic or sacred structure or feature that is being used for military purposes has to be made at the highest levels.

Stabilization and Post Conflict

The final phases of military operations are designed with the hope of restoring social order within the conflict zone. If material heritage within the landscape of a crisis zone has survived, there is increased hope that the community may recover as a corporate entity.

Blue Shield Committees

During the conflict in the Balkans, it became clear that 1954 Hague and its First Protocol, as designed and written, were insufficient to address destruction of cultural property as related to

genocidal and ethnic conflicts of the late twentieth century. As a result, they were supplemented with a second protocol drafted in 1999. In addition, in 1996, representatives of four nongovernmental organizations representing people active in the fields of archives, libraries, monuments and sites, and museums formed the International Committee of the Blue Shield (ICBS). Later the Coordinating Council of Audiovisual Archives Associations signed on as well. In 1999, the Second Protocol established the Intergovernmental Committee for the Protection of Cultural Property in the Event of Armed Conflict and articulated an official role for the ICBS as an advisory group to the Committee. The ICBS adopted a charter in 2000, and one of its key functions was to encourage establishment of national committees of the Blue Shield. Since that time, 26 countries have established committees, while another 22 countries have committees under construction (USCBS 2017). National committees of the Blue Shield are the organizations designated by the Second Protocol to assist and support military efforts to implement meaningful cultural property protection programs. It should also be mentioned that 1954 Hague establishes the Blue Shield as the recognized international symbol designating protected cultural property. The symbol is intended to be used the same way red crosses and red crescents are used to designate protected medical facilities.

The United States

As mentioned above, USCBS is playing a very active role in providing cultural property inventory information to US DIA. In addition, USCBS successfully advocated for US Senate ratification of 1954 Hague and currently encourages increased defense implementation of convention responsibilities at the legislative level. USCBS partners with other organizations whenever possible to assist with military training and development of educational materials.

The United Kingdom

The UK Committee of the Blue Shield has recently made remarkable progress. As advocates for CPP, this committee encouraged not only ratification of 1954 Hague and its two protocols by the UK Parliament but also insured passage of enabling legislation for establishment and implementation of a meaningful military CPP program. As a result, the UK is in the process of establishing a force of reserve officers who will serve as modern monument officers. The UK committee is also continuing to cooperate on collection and sharing of cultural property inventory information.

Norway

The Norwegian Blue Shield Committee was formed in 2000. This committee has worked to protect cultural property in conflict zones like Iraq, Afghanistan, and the West Bank while also strengthening their domestic program for development of an emergency plan for protecting cultural heritage in the event of a disaster. In addition, the Norwegian committee developed a deck of bilingual English and Norwegian archaeological awareness playing cards for military personnel based on the examples of the US decks. The President of the Norwegian Committee of the Blue Shield serves as a key board member of the new International Blue Shield organization that emerged out of the Associated National Committees of the Blue Shield (Mickleby 2015).

Switzerland

Given its neutrality, Switzerland focuses on civil defense in terms of its approach to military capability. Within this context, the Swiss have established a strong committee of the Blue Shield and associated program. Swiss Civil Defense utilizes civilian subject matter experts by providing them an opportunity to serve in their professional capacities as military experts. As a result, the Swiss are able to benefit from preservation expertise as they implement cultural property protection in the military context. In 1966, the Swiss passed the Federal Protection of Cultural Property Act and, nearly 20 years later in 1984, an enacting decree. They produced their first "Inventory of Cultural Property of National and Regional Importance" in 1988 and revised it in 1995. In 2009, they added an inventory of all museum collections to their system. Their protection system is applied at all levels of government, federal,

canton, municipal, and at the very local level, and emphasizes interagency and interdisciplinary partnerships (Zellmeyer 2010; Federal Office of Civil Protection 2017).

In terms of military participation, cultural property protection training is mandatory for all Swiss military personnel. The Swiss offer a 5-day course three times a year, and they have specialized officers and a CPP manual. Given the focus on civil defense, the Swiss are beginning to shift their military focus from potential deployment and conflict to effective disaster response. In 2012, the Basel library used its disaster plan to assist in developing a "Guidelines for the Preparation of a Disaster Plan." In addition, the Swiss Committee of the Blue Shield has established a quarterly publication that offers excellent advice on protecting and preserving cultural property (Swiss Committee of the Blue Shield). This publication, with articles and abstracts in four languages, English, Italian, French, and German, focuses on a different aspect of cultural aspect of CPP in each issue. Examples of topics include Documentation of Cultural Property, Protection of Archaeological Sites, Protection of Natural History Objects, Response to Natural Disasters, and Protection of Cultural Property during Conflict.

NATO CPP Project

NATO forces demonstrated the effectiveness of using archaeological site data to influence targeting decisions during Operation Unified Protector in Libya in 2011. Using information contributed by archaeologists from the United States and the UK, NATO planners were able to incorporate the locations of key archaeological sites along the Mediterranean coast into the battle plans. Even though Gaddafi had placed military targets like radar installations on archaeological sites and ancient structures, damage was minimized because the aircraft crews knew the areas to avoid. An international Blue Shield mission to Libya confirmed site integrity upon conclusion of the conflict, and these results were reported at a conference at the American Academy in Rome in November of 2011 (D'Emilio 2011). The resulting positive global media coverage encouraged the US DIA to increase its commitment to protection of cultural property and eventually led to funding for the NATO Science for Peace and Security, "Cultural Property Protection Policy, Doctrine, and Best Practices Project."

In essence, all 24 NATO nations voted to support a series of advanced research workshops designed to develop policy, doctrine, and best practices for effective implementation of a cultural property protection program for the Alliance. Workshop participants, led by a co-director from Denmark, included staff from NATO headquarters as well as high-ranking officers from the Supreme Headquarters Allied Powers Europe (SHAPE), academic archaeologists, and military personnel representing more than ten countries. Discussions included mapping, military education, and development of policy, doctrinal, and guidance documents. Project outcomes include establishment of a cultural property geo-spatial data layer for future NATO operational maps, a cultural property protection handbook for military personnel, and recommendations for future NATO policy development, possibly in the form of a Standardized NATO Agreement or STANAG. The final project report will be publicly released and the handbook available for digital distribution to military personnel in the fall of 2017. During the course of the NATO project, two retired US Navy Commanders presented a prototype of a cultural property protection video game that could be used for military training. UNESCO is looking for a country sponsor to support development of the game for global distribution.

Creation of the cultural property geo-spatial data layer at NATO is especially important because it sets a new standard for the field of military "human terrain" mapping. When the discipline of human terrain mapping for military applications emerged in the early 2000s, geographers agreed on features they viewed as essential for meaningful mapping models like ethnicity and language distribution. Inexplicably, they never included a cultural property or monuments geo-spatial data layer (WWHGWG 2016; NATO GIS Workshop 2016). As a result, military

requirements for "human terrain" maps were missing those critical data points. The closest category available for mapping an archaeological site was "land use." As a result, for an entire decade, military maps prepared for US personnel were missing critical cultural property information including locations of some of the most important archaeological sites in the world. When we combine NATO's new mapping initiative with the work of Blue Shield Committees who are supplying archaeological information to Defense Intelligence, there is reason to be more optimistic about the planners of future military operations having much more critical information concerning sensitive sites and cultural property in their areas of responsibility.

The NATO Center of Excellence for Stability Policing (COESPU) located in Vicenza, Italy, has shown a special interest in supporting international efforts for archaeological site and heritage protection. Stability police are responsible for local policing capacity building, and the international police recognize that in many areas in the immediate aftermath of conflict or disaster, protection of archaeological sites, museums, and other locations related to heritage can result in more rapid return to social order and cohesion within a community. As a result, military personnel dedicated to stability policing have included CPP as part of their core competence and have developed programs for educating host nation police on not just the importance of protecting archaeological sites but also methods for doing so.

UNESCO

When various extremist organizations began to destroy archaeological sites and museums in very public ways, the United Nations Educational, Scientific and Cultural Organization (UNESCO) became increasingly interested in working with military organizations under the rubric of International Laws of Armed Conflict (LOAC). In 2015, they established the first ever UNESCO Chair in Cultural Property Protection and Peace at Newcastle University, UK. They have a goal of developing CPP training and educational materials that can be distributed worldwide, and they published the Protection of Cultural Property Military Manual (O'Keefe et al. 2016) which can be downloaded at http://unesdoc.unesco.org/images/0024/002466/246633E.pdf. This manual covers legal obligations for responsible military organizations to protect cultural property during the course of armed conflict.

When Islamic extremists began attacking Sufi Tombs, sacred sites, and libraries in northern Mali and Timbuktu, UN resolution 2100 established the peacekeeping force MINUSMA, designed to restore social order. Resolution 2100 specified that the force was "to assist the transitional authorities of Mali, as necessary and feasible, in protecting from attack the cultural and historical sites in Mali, in collaboration with UNESCO." This resolution marked the first time in modern history where protection of cultural property was specified in the military mission. The MINUSMA forces discovered that the increased patrols and demonstration of concern and protection for the tombs, mosques, libraries, and archaeological sites resulted in improved acceptance of the foreign peacekeepers by the Malian people (UNESCO 2014). With support from UNESCO, the Malian Ministry of Culture created the Passport pour le Patrimoine, a graphic training aide for military personnel that provided maps of Timbuktu, Gao, and Kidal with photographs and locations of the most important cultural sites. The enthusiastic reception and use of this document inspired the Conflict Culture consortium with support from the US State Department to duplicate the concept by preparing similar guides for Mosul and Raqqa. These guides are trilingual in English, Arabic, and Kurdish for use by US, Iraq, and Peshmerga forces.

UNESCO has also established UNITE4Heritage, www.unite4heritage.org/en/unite4heritage-celebrating-safeguarding-cultural-heritage, a global movement that "calls on everyone to celebrate the places, objects and cultural traditions that make the world such a rich and vibrant place." One of the most exciting initiatives taking place under the aegis of UNITE4Heritage is the Italian "Blue Helmets for Culture" program. This project with the support of the University of

Turin and La Venaria Reale Consortium has created and trained a deploying force of approximately 60 people of Carabinieri and Italian military partnered with heritage professionals. The Carabinieri TPC regional office in Turin was also a key participant, especially in the training portion. This force is available to go anywhere in the world when called upon at the behest of the UN and/or a country that has asked for assistance.

UNESCO has also become interested in the challenge of military training and education. UNESCO has funded development of training materials for military personnel and is beginning to experiment with implementation by offering workshops for peacekeeping forces. The first such course was successfully completed at the Regional Peacekeeping Training Center in Harare, Zimbabwe, in September of 2017.

Into the Future

Injects

In addition to providing information and lectures, archaeology partners have assisted in development of a range of methods for educating military personnel about cultural property. There are slide presentations, case studies for formal use in the classroom, and scenarios where soldiers can practice identification and appropriate response to archaeological sites and cultural property in the field. One of the most effective ways to train military personnel is to offer them opportunities to actually practice CPP skills during the course of military field exercises. When a special challenge is introduced into an exercise in order to add realism to the training experience, it is called an "inject." As awareness of the importance of cultural property increases, we are beginning to see inclusion of cultural property injects into actual military exercises. In the summer of 2015, NATO added two cultural property injects into exercises taking place in Northern Europe. One of the challenges offered a situation where a historic castle was occupied by adversaries and friendly forces needed to secure it with a minimum of damage. A second challenge resulted from a fictitious situation where a large convoy of heavy military vehicles was traveling too close to a very old church and the vibration was threatening to break the stained glass windows. The operation planners had to figure out a new route in order to solve the problem.

The US Army recently added a cultural property inject to a major division exercise. In this case, Fort Drum used a combination of actual archaeological sites and replica ruins to challenge the brigade commander with two requests from the local population. The first request asked the commander to report on the condition of the archaeological sites that were located in territory recently retaken from the adversaries. The second was a request for recovery of artifacts stolen by insurgents who had destroyed the local museum. Injects of this nature benefit the military in a number of ways. First, it increases awareness of the importance of cultural property for a force preparing to deploy. Second, an unexpected challenge encourages different elements of the force to work together in creative ways to solve the types of problems they are going to encounter in crisis areas. When confronted with the challenge of stolen artifacts, military police, civil military personnel, intelligence officers, and military legal advisors all worked together to develop a recovery plan that involved the entire force who were instructed to identify high-value enemy targets who may have been carrying the stolen objects. Ultimately, recovery of cultural property also offers the military a powerful strategic communication advantage.

Conclusion

As we think about the changes since archaeologists began to think about protection of archaeological sites in the context of conflict in the early 2000s, there is now cause for optimism. We see programs emerging not just among forces of the major powers but also in many nations all across the globe. We see the results of academic and

military partnerships in a host of creative approaches to working together. In summary, a military force that is able to demonstrate respect for local populations, heritage, and values immediately distinguishes itself from destructive, genocidal, and extremist adversaries, an important accomplishment indeed.

M

Miller, Margaret C.

Margaret Cool Root
Department of the History of Art, the Interdepartmental Program in Classical Art and Archaeology, and Kelsey Museum of Archaeology, University of Michigan, Ann Arbor, MI, USA

Basic Biographical Information

Margaret C. Miller (Fig. 1) is a prolific classicist and interpreter of the visual/material record of archaic and classical Greece. Her dynamic

Miller, Margaret C., Fig. 1 Margaret C. Miller

approach to Greek cultural perspectives on the Achaemenid Persian empire is an especially important feature of her work. Miller was born in Liverpool but soon emigrated to Canada, where she was raised and educated through the B.A. degree (Honours Classics) at the University of British Columbia. Following a second degree at Oxford and a year-long fellowship at the American School of Classical Studies at Athens, she earned her Ph.D. at Harvard University under Emily Vermeule in 1985. She has participated in archaeological projects in Greece (Mytilene and Corinth), Turkey (Sardis), Egypt (Naukratis), and England (Wroxeter). Since 2012, she is codirecting a collaborative field project at Zagora (Andros).

A distinguishing feature of Miller's professional contributions to date lies with her skills as an administrator as well as a scholar and subtle thinker. She taught at the University of Toronto, Department of Fine Arts, from 1989 to 2005, serving as Chair from 1996 to 2000. She has been on the faculty of the University of Sydney, Department of Archaeology, since 2005 as Arthur and Renee George Professor of Classical Archaeology (Head of Department for part of that time). She has consistently participated on many archaeological committees, most recently adding to her dossier of such activities the Headship of the Australian National Committee of the *Corpus Vasorum Antiquorum* and Membership on the Executive Committee of the Australian Archaeological Institute of Athens.

Major Accomplishments

Miller's first book, *Athens and Persia in the Fifth Century B.C.: A Study in Cultural Receptivity* (1997/2004), established her as a brilliant mind solidly informed by rigorous training in Greek literary and material culture and attunement to issues of intercultural arenas of social contact and exchange between Greece and the Achaemenid Persian empire. Key to the importance of *Athens and Persia* – what has made it a true classic in the field – is the nuanced approach Miller takes to notions of influence as a fluid system rather than a one-way exertion of cultural authority. This book was awarded *Le pris Roman and Tania Ghirshman* from the Académie des Inscriptions et Belles Lettres, Paris, in 2001. Supporting its overarching intellectual mandates are a series of impressive articles on specific topics relating to Greek-Persian cultural entanglements discernible through the visual/material record from pottery and luxury paraphernalia, to costume and sartorial accouterments, to cultural performance (e.g., among others, Miller 1989, 1992, 1993, 2010a, 2011a). Other major articles and chapters pursue a range of topics primarily working across similar platforms of evidence but focusing principally on Greek perspectives (e.g., 1999, 2008, 2010b, 2011b). Another side of Miller's scholarship, particularly in collaboration with Eric Csapo, explores Greek drama and ritual and theories of art- and myth-making as social practice (e.g., 2007).

Professor Miller has won numerous postdoctoral research grants and fellowships: five from the Social Sciences and Humanities Research Council (Canada), two from the National Endowment for the Humanities (USA), one from Harvard's Center for Hellenic Studies (Washington DC), and one from the Australian

Research Council. Two book projects forthcoming involve studies of Persians in the Greek imagination and iconographies of orientalization in Greek myth as represented in Attic art.

Millets: Origins and Development

Dorian Q. Fuller
Institute of Archaeology, University College London, London, UK

Basic Species Information

Millet is an imprecise English term applied to a large number of smaller-grained, largely tropical cereals that are often distantly related. Millets tend to be small-seeded cereals, i.e., distinct from wheat, barley, oats, rice, and maize. Sorghum is sometimes included with millets (in Indian English it is the "great millet"). Taxonomically speaking "millet-grasses" refers to grasses in the Panicoid subfamily and the Paniceae tribe, but not all traditional millet crops are in this group. Finger millet (*Eleusine coracana*) and tef (*Eragrostis tef*) are in the Chloridoid subfamily. Although a few millet species have been cultivated in Europe, they are generally less important economically and culturally, leading to poor linguistic differentiation in European languages, e.g., French *millet*, German *hirse*, and Spanish *mijo*.

Millets have received far less research than the "big" cereals (rice, wheat, and barley). Indeed statistics on millet production are very poor, as they are grouped as "minor cereals" in most national and FAO statistics. This is, at least in part, the product of a historical European bias against millets, especially among the former colonial powers of Northern and Western Europe, where millet cultivation is negligible. These cereals were undervalued and under-researched in the colonial period which set an unfortunate

precedent for modern governmental and non-governmental agricultural organizations. There are several "lost" or disappearing millets, cultivated in very localized areas or documented archaeologically only. This includes the recently "rediscovered" *Spodiopogon formosanum* of Taiwan (Takei 2008), the now relict browntop millet of South India (*Brachiaria ramosa*) (Fuller 2006), the local domesticate "raishan" (*Digitaria cruciata*) of the Khasi Hills in northeast India (Singh and Arora 1972), the black fonio (*Brachiaria deflexa*) and iburu (*Digitaria iburu*) of West Africa (Harlan 1992), the Sonoran millet of the American Southwest (*Panicum sonorum*), and the no longer cultivated crabgrass millet of Southeastern Europe (*Digitaria sanguinalis*) referred to in historical sources ranging from late Roman times to the nineteenth century (De Wet 2000).

Major Domestication Traits

There are at least 18 domesticated and cultivated species of millet, listed below in Table 1, together with a few other "minor cereals." These have been domesticated on almost every continent that had prehistoric agriculture, with the possible exception of Europe (De Wet 2000; Weber and Fuller 2008). Even in the case of the obvious exception of Australia, several wild millet grasses are reported to have been regularly gathered as a carbohydrate source of some Australian Aboriginal groups (Harris 1984). Similarly wild seed gathering in Africa often targets wild millets (Harlan 1992). In many cases, closely related species, in the same genus, have been domesticated independently on different continents, such as *Panicum* domestications in North America, India, and China; *Digitaria* and *Brachiaria* domestications in Africa and South Asia; *Setaria* domestications in China, India, and Mesoamerica; or *Echinochloa* domestications in South Asia and Japan. Thus, millets illustrate the parallel evolution of domesticates and cultivation systems from similar wild materials. Millets contributed to the earliest agriculture in several parts of Eurasia, including northern China, where millet cultivation developed well before rice was introduced (Zhao 2011), Korea, parts of Japan, and various parts of India (Fuller 2006). There may also be an early millet center in Western/Central Asia (the Caspian/Ukraine region) to account for Neolithic *Panicum* dispersal into Europe. In Africa numerous millets were domesticated in various parts of the Savannah zone, in the West African Sahel, and in the Ethiopian highlands.

Millets represent a diverse group of versatile cereals that have long been a part of many agricultural ecologies in Eurasia and Africa, but especially in more arid and tropical regions. Millets are generally well adapted to low-rainfall regimes, short growing seasons, and poor soils (Bhag et al. 2010). They are therefore often the most reliable cereals in many marginal environments. Most millets are reported to be drought tolerant, although a few such as finger millet (*Eleusine coracana*) are usually grown in somewhat wetter conditions and on good soils in order to produce high yields. At the more extreme end of drought tolerance are *Panicum miliaceum* in Eurasia and *Pennisetum glaucum* in the hot and dry parts of Africa and India, both of which may grow with 300 mm of rainfall or less and mature rapidly (within 3 months).

Millets present a challenge archaeobotanically as the grains of several species are somewhat similar and may be especially difficult to differentiate in carbonized material in which the husk is absent. This has led to a discussion of the misidentification problem, with one millet species being reported as another (e.g., Hilu et al. 1979; Fuller 2006). There has also been recent recognition of unfilled (immature) grains that may be common at archaeological sites and may have sometimes been mistakenly grouped with other taxa (Song et al. 2013).

Those millets with better archaeological records are treated in separate entries in this encyclopedia, including browntop millet (*Brachiaria ramosa*), broomcorn millet (*Panicum miliaceum*), finger millet (*Eleusine coracana*), foxtail millet (*Setaria italica*), little millet (*Panicum sumatrense*),

Millets: Origins and Development, Table 1 Millets: taxonomy, common names, and regions of origin

Species	Common name	Region of origin and cultivation
Brachiaria ramosa (L.) Stapf. (syn. *Urochloa ramosa* (L.) R. D. Webster)	Browntop millet, pedda-sama	South India
Brachiaria deflexa (Schumach) C. E. Hubbard var. *sativa* Porteres	Guinea millet, animal fonio	Fouta Djallon highlands, Guinea, W. Africa
Bromus mango E. Desv.	Mango	Andes (Peru). Not taxonomically a millet but a now extinct minor cereal cultivar
Digitaria cruciata (Ness) A. Camus var. *esculenta* Bor	Raishan	Khasi Hills, Assam; Hill tribes of Vietnam
Digitaria exilis (Kippist) Stapf.	Fonio, acha, fundi	West Africa
Digitaria iburua Stapf.	Black fonio, iburu, hungry rice	West Africa
Digitaria sanguinalis (L.) Scop.	Harry crabgrass	Eurasian origin; cultivated in Kashmir, formerly in Europe
Echinochloa colona (L.) Link ssp. *frumentacea* (Link) De Wet, Prasada Rao, Mengesha and Brink (= *E. frumentacea* Link).	Sawa millet	Peninsular India(?), also cultivated in the Himalayas
Echinochloa crus-galli (L.) P. Beauv. subsp. *utilis* (Ohwi & Yabuno) T. Koyama (syn. *E. esculenta* (A. Braun) H. Scholz)	Barnyard millet	Japan
Eleusine coracana (L.) Gaertn.	Finger millet, ragi	East African highlands
Eragrostis tef (Zucc.) Trotter	Teff	Ethiopian highlands
Panicum miliaceum L. ssp. *miliaceum*	Proso millet	China and SE Europe(?)/Caucasus; cultivated throughout South Asia
Panicum sonorum Beal (=*P.hirticaule* J. Presl. var. *millaceum* (Vasey) Beetle)	Sauwi millet, Sonoran millet	American Southwest
Panicum sumatrense Roth. ex Roem. & Schult. Subsp. *sumatrense* (syn. *P. miliare* auct. pl.)	Little millet, samai	India, especially peninsula
Paspalum scrobiculatum L.	Kodo millet	India, especially peninsula, and the Himalayas
Pennisetum glaucum (L.) R. Br (= *P. americium* (L) Leeke)	Pearl millet	West African Savannah, cultivated through India
Setaria italica (L.) P. Beauv ssp. *italica*	Foxtail millet	China and SE Europe(?)/Caucasus, cultivated throughout South Asia and in parts of Southeast Asia
Setaria palmifolia (J. Koenig) Stapf	Highland pitpit	Papua New Guinea; cultivated as a green vegetable
Setaria macrostachya Humboldt, Bonpland & Kunth	*Ne-kuuk-suuk* (Mayan)	Mesoamerica, cultivated(?) before rise in importance of maize
Setaria parviflora (Poir.) Kerguélen	Knot-root foxtail	Mesoamerica
Setaria pumila (Poir.) Roem & Schult. (syn. *S. glauca* auct. pl.) (Domesticated population reported)	Yellow foxtail millet, korali	India
Setaria sphacelata (Schumach.) Stapf & C. E. Hubb.	African bristle grass	Sudan: "lost millet" of Nubia
S. verticillata (L.) P. Beauv. (Domesticated populations?)	Bristley foxtail millet	South India
Sorghum bicolor (L.) Moench ssp. *bicolor*	Sorghum, jowar	African Savannahs, cultivated throughout South Asia
Spodiopogon formosanus Rendle	Taiwan hill millet	Cultivated in uplands of Taiwan for Formosan-speaking groups

kodo millet (*Paspalum scrobiculatum*), pearl millet (*Pennisetum glaucum*), and sorghum (*Sorghum bicolor*).

Hayashi Minao

Junko Uchida
Institute of History and Philology, Academia Sinica, Taipei, Taiwan

Basic Biographical Information

Hayashi Minao was born on 5 May 1925 in Fujisawa city, near Kamakura, Kanagawa Prefecture, Japan. His father, Tatsuo Hayashi, was a famous critic, and he nurtured his interests in humanities under his father's influence. He became interested in pre- and protohistoric Chinese artifacts and motifs under the tutorage of Sueji Umehara, Professor at the Department of Archaeology, Faculty of Literature, in Kyoto University. He obtained his BA degree in 1950 and Ph.D. in 1975, both from Kyoto University. After working as an editor at Heibonsha Ltd. for a short while, in 1957 he accepted the position of a research assistant (1957–1968) at Kyoto University Research Centre for the Cultural Sciences. He was promoted to associate professor in 1968 and professor in 1975. After retiring from Kyoto University in 1989, he was decorated with the Japanese Third Order of Merit in 1995 and became a member of the Japan Academy in 2004. He passed away on 1 January 2006.

Major Accomplishments

Hayashi conferred that he was fond of G. W. F. Hegel's writings in his youth. In his

writings Hayashi tried to approach to the essential character of Chinese artifacts and the Chinese culture itself. This can be explained by his inclination to Hegel's idea of the essential nature of human subjectivity and its evolution.

In his first article, entitled "Ryu ni tsuite (A study of the dragon motif)" (1952), Hayashi tried to trace the original meaning of the dragon motif back to the Chinese classical literature by investigating the chronological sequence of the dragon motif in the material culture.

From his first article, Hayashi continued investigating the ideological and religious implications and roots of Chinese artifacts until the end of his life. He tried to reconstruct the symbolic and religious meanings of artifacts and their evolution by studying the sequential transformation of various representative motifs on carved stelae, bronze vessels, jade artifacts, lacquerware, silk textile, and so on, dating between the Neolithic and the Han dynasties (e.g., 1976, 1989b). Hayashi single-handedly constructed the typo-chronological system of the bronze vessels between Yin-Zhou and Warring States periods (1984, 1986, 1989a), the chariots and armors of the Yin-Zhou period (1972), and the jade artifacts of the Neolithic through Han dynasty periods (1991, 1999) by compiling respective compendia of photographs and drawings of artifacts, some unearthed in scientific excavations and others housed in museums across the world as collected items. Those monumental works remain today as most authoritative references of the respective items and are used for the dating of newly excavated items.

Hayashi also innovatively used Chinese classical literature such as *Mountains and Seas* (山海経), *Er-ya* (爾雅), and *Shuowen Jiezi* (説文解字) in his reconstructions of the name, function, and meaning of artifacts and motifs.

Hayashi's goal was always to understand the essential character of the Chinese culture, and he reached the conclusion that it was the sense of awe in relation to various natural phenomena, formalized in the system of symbolic concepts, that formed the foundation of a unique animistic belief system, constituting the basic undercurrent of the Chinese culture. His method was culture-historical, but his approach and objectives, in that sense, were social anthropological (Fig. 1).

Mineralization of Macrobotanical Remains

Charlene Murphy
Institute of Archaeology, University College London, London, UK

Introduction

Limited research has been conducted on the factors influencing the process of mineralization of macrobotanical remains on archaeological sites. A few studies have focused on mineralization from archaeological contexts, including the common process of calcium carbonate ($CaCO_3$) replacement in arthropods, such as woodlice, millipedes, and centipedes (Girling 1979: 309; McCobb et al. 2001) and a few studies on seeds (Ciaraldi 2001, 2007; Green 1979; Kenward and Hall 2000; Marshall et al. 2008).

Definition

Mineralization is a naturally occurring complex process in which phosphate and mineral deposits replace minerals from decaying organic matter. Phosphatization, the releasing of phosphate ions, from a variety of sources including faunal remains, food residues, and excrement, is thought to be caused by microbial decay and the movement of the dissolved ions facilitated by fluctuating water levels within the archaeological deposit (McCobb et al. 2001; Marshall et al. 2008: 860; Robinson et al. 2006: 214). Within an archaeological setting, possible sources of phosphate and calcium include human fecal material from specific archaeological deposits such as middens, latrines, and cesspits (a kind of soakaway: liquid material seeped into the ground while solid material remains in the pit (Jansen 2000: 37–9, 2002: 27)), mammal bones, fish bones and scales, and plant material (Carruthers 2000 cited in Ciaraldi 2001: 66). Archaeologically, without sewage, the occurrence of mineralization is extremely low.

The process of phosphate mineralization requires a liquid medium to be able to fully engulf an item so that the ions can diffuse and become concentrated and result in the precipitation of calcium phosphate (Marshall et al. 2008: 860). The phosphate ions react with the calcium ions from calcium carbonate, which can come from different sources within the deposit including limestone or mortar fragments, human fecal material, shells of marine molluscs, fish scales and bones, faunal remains, or the leaching of natural substrate in contact with the deposit (Robinson et al. 2006: 214). The result is a cast of the organic material called a pseudomorph, which is reproduced in various degrees of perfection (Green 1979: 282, 284).

Due to their small size, seeds which possess an intact seed coat and fly puparia, with tough larval skin, are particularly well suited to preservation through this process (Robinson et al. 2006: 215). Factors such as the original percentage of calcium minerals in, and thickness of the seed's testa, the presence and amount of cuticles, lignin, and tannins within the cellular structure, and the decomposition of organic material, all impact upon the overall mineralization process (Girling 1979; Miksicek 1987; Carruthers 2000; McCobb et al. 2001; Ciaraldi 2007: 49–50). Seeds which have become mineralized typically consist of light inorganic material with a poorly defined crystalline apatite structure. The main constituent is calcium phosphate, $Ca(PO4)_6(OH)_2$, visible using X-ray diffraction, which is normally light brown, honey-colored to white in color (Green 1979: 279–281). There appears to be a bias toward seeds which are swallowed intact, such as fig achenes, and grape pips (Cool 2006: 119; Robinson et al. 2006: 215). Millets are often recovered in a mineralized state due to the fact that some millets retain their

Mineralization of Macrobotanical Remains, Fig. 1 (**a**, **b**) Mineralized Ficus carica (fig) from Insula VI.I (scale in centimeters). (Photo by author) N.B Mineralized fig pips retain their characteristic pyriform shape

indigestible hull (lemma and palea) even after dehusking. Being quite small, millet grains with their intact pericarp, can pass through the human gastrointestinal tract and facilitate the mineralization process. Hence, seeds with intact thin cell walls such as fig and apple seeds which also pass through the body are much more likely to be preserved through mineralization. As van der Veen et al. (2008: 84) demonstrated in their comprehensive statistical analysis of archaeobotanical remains from Roman Britain, there is a strong correlation between plant type and preservation. A similar pattern is seen in the archaeobotanical assemblages from Insula VI.I, Pompeii, Italy, as carbonized archaeobotanical material is typically composed of olives and fruits and mineralized archaeobotanical material of small fruits seeds such as grape pips and fig achenes (Murphy et al. 2012) (Figs. 1, 2, 3 and 4).

According to Green (1979: 281), a number of factors influence the process of mineralization including soil type, type of organic refuse present, and sufficient circulation of groundwater. Kenward and Hall (2000: 519, 2008: 586) suggest that urban occupation deposits, with their variation in sedimentology and chemistry on a minute centimeter scale, present a more complex set of problems, with regard to the process of mineralization, than rural sites. Within urban occupation deposits, organic material is often preserved via anoxic water logging. Complete water logging otherwise impedes the process of mineralization. However, it appears that the process of mineralization is enhanced by the partial water logging of botanical materials

Mineralization of Macrobotanical Remains, Fig. 2 SEM of one mineralized Ficus carica (fig) from Insula VI.I. (Photo by the author)

under anaerobic conditions (Briggs and Wilby 1996 cited in Ciaraldi 2007: 49–50); although no firm scientific preservation model for the mineralization of organic deposits has been established to date (Kenward and Hall 2008: 588).

Examples

Case Study

In Pompeii, the mineralization of organic remains happens through the process of phosphatic mineralization. The majority of mineralized remains

Mineralization of Macrobotanical Remains, Fig. 3 Mineralized Agrostemma githago L. (corn cockle) from Insula VI.I. (Photo by the author)

Mineralization of Macrobotanical Remains, Fig. 4 Mineralized lentil recovered from Insula VI.I. (Photo by author)

were composed of fruit, particularly small seeds, which pass through the human digestive system and are preferentially preserved. Ciaraldi's Pompeiian studies (2001: 150–151; 2007: 49–50) found that the unique taphonomy created by the copious ash and lapilli from the numerous volcanic eruptions and the alkaline volcanic soils surrounding Mount Vesuvius resulted in an archaeological matrix rich in calcium phosphate minerals.

Toilets in the kitchen area were a common feature of Pompeian households (Hobson 2009; Jansen 2001: 38). They were strategically placed in or near kitchens allowing for the disposal of burnt kitchen waste. The presence of carbonized material including nuts, weeds, and cereals testifies to this fact. Roman writer Columella mentions the usefulness of ashes as a "disinfectant," "cleaning agent," and "odor suppressant." Deposition of ashes from the cooking area into the latrine may have contributed to the mineralization process as potash, which contains potassium or potassium carbonates in water-soluble form, which along with the high percentage of organic matter in the latrine would have facilitated mineralization (Ciaraldi 2001: 67; Green 1979: 279). This could have contributed to the number of mineralized taxa recovered from this deposit. The mineralized latrine assemblage from the House of the Vestals (VI.I.vii) showed similar characteristics with the mineralized deposits from the House of Hercules' Wedding (VII.IX. x1vii) in which cereals were virtually absent and fruits and weeds were abundant. This is typical of the preservation found among mineralized contexts (Ciaraldi 2001: 149–152).

Pedological analysis at Pompeii showed that similar soil compositions are present today as in the past: loamy sand to sandy loam, with a high percentage of extractable nutrients and moisture retention capabilities with abundant ash and pumice present (Ciaraldi 2001: 66, 2007: 49; Foss 1988: 133; Foss et al. 2002: 77–78). Hence, one theory regarding mineralization is that calcium in the subsoil is dissolved into solution by a reaction of percolating ground water on available sources of phosphate (Green 1979: 281). The mineralization process was likely facilitated by a combination of mineral and volcanic ash, as well as partial water logging and leaching of unique contexts of

drains and cesspits. Exposure to large quantities of calcium phosphates produces higher quantities of mineralized material. This can be seen in specific deposits from the House of the Vestals (VI.I.vii), as identified and analyzed by Ciaraldi (2001: 162–163), including the drains which span over a century and the toilet feature.

Ciaraldi (2001: 67, 2007: 49–50) argued that some samples from the House of the Vestals (VI.I.vii) underwent water logging during stages of mineralization as a differential density of the mineralized archaeobotanical material was visible through the depth of a deposit. She hypothesized that a liquid medium facilitated this downward movement of heavy preserved botanical material. All seeds were counted, but no mention was made of either the weight or size of the seeds in this analysis. Ciaraldi (2007: 49–50) also observed aggregations of calcium phosphate minerals having vague shapes of seeds within waterlogged samples from the Villa Vesuvio. Again this suggests a possible correlation between mineralization and water logged botanical material. High temperatures are also thought to facilitate the deposition of minerals on organic material, and thus, the high temperatures during the summer months in Campania may have accelerated this process of preservation within the upper soil horizon (Ciaraldi 2001: 67, 2007: 50).

Misra, Virendra Nath

Manoj Kumar Singh
Department of Anthropology, University of Delhi, Delhi, India

Basic Biographical Information

Virendra Nath Misra (Fig. 1) was born on 17 August 1935 to a farming family in Kandauli village in Farrukhabad district of Uttar Pradesh. In 1951 he became the first student from his village to graduate from high school, which he did at Rastogi School (latter K. R. Rastogi Inter College), Farrukhabad. In 1953 Misra passed his intermediate examination as well as the *Visharad* examination of Hindi Sahitya Sammelan, Allahabad. In 1954 he stood in first position and passed the *Prarthana* certificate examination in Sanskrit from the Government Sanskrit College, Banaras, and won a four-year government scholarship to pursue further studies in Sanskrit. He passed his B.A. entrance examination in 1955 and joined Lucknow University in 1955. He was awarded a two-year bursary scholarship from Lucknow University in recognition of his performance at the B. A entrance examination. He passed his M.-A. entrance examination in 1957 and stood first in order of merit in his class. For his performance he won the Pandit Jagpal Krishna Gold Medal. He also passed the *Purva Madhyama* exam in Sanskrit from the Government Sanskrit College, Banaras.

Misra, Virendra Nath, Fig. 1 Photo of Misra

After his M.A., Misra was appointed as a lecturer with the Anthropology Department at Lucknow University, where he taught prehistoric archaeology and social anthropology to B.A. and M.A. students. He got Ph.D. in 1962 from Poona University. On 15 July 1961, he was appointed to an assistant professor's post at Lucknow University and in 1962 he was awarded his Ph.D by Poona University.

From 26 July 1962 to 1981 V.N. Misra was a member staff with the Department of Archaeology, at Poona University, first as a lecturer (1961–1968) and then as reader and head of department (1968–1981). He later stated that he preferred Pune University to Lucknow University due to better facilities and atmosphere. V.N. Misra also passed certificate courses in French and German from Poona University and Max Mueller Bhavan (Goethe Institute) in 1966 and 1971, respectively, and undertook course in Russian at Poona University. In 1981 he joined Deccan College at Pune as a professor of prehistoric archaeology. Again in 1983 V.N. Misra joined the Department of Anthropology at Lucknow University on September. In 1986 he became Joint Director at Deccan College and Director of the College in 1990. He retired from the latter post on 31 August 2000. He was the editor of *Indian*

Society for Prehistoric and Quaternary Studies (ISPQS) in 1989 and also general secretary of the society from 1981 to 2000. Since 2001 he has been the president of the society.

Major Accomplishments

V. N. Misra's career in archaeology has been undertaken during a period of major change in Indian archaeology. During his lifetime many new sites have been discovered and explored. His accomplishments have been achieved local, national and international levels. V.N. Mishra's contributions to archaeology in India started early in his career. During his M.A. he participated in Sankalia's excavation of the Chalcolithic site of Navdatoli in Madhya Pradesh during December 1958. After that, he proceeded to Chittorgarh in Rajasthan in January 1959 and explored Paleolithic sites in the Gambhiri and Berach rivers. From Chittorgarh (Chitorgarh) he went to Pali in western Rajasthan (across the Aravalli Hills) to explore in the Luni River and its tributaries. Through field work in this area and in the valleys of the Banas River and its tributaries in eastern Rajasthan he discovered 14 Lower Paleolithic, 18 Middle Paleolithic, and 4 Mesolithic sites besides a number of Paleolithic and Mesolithic sites which had been discovered by M. N. Deshpande, S. R. Rao, and K. N. Puri of Archaeological Survey of India (ASI) in the valleys of the Chambal rivers and Banas rivers and their tributaries around Chittorgarh. While undertaking his doctoral studies, V.N. Misra wrote a major treatise on the Paleolithic industry of Western Rajputana, which was published in the *Bulletin of the Deccan College* (Misra 1962).

During 1964 and 1965 V.N. Misra analyzed the material from his Rajasthan field work and wrote several articles for different journals and a monograph entitled *Pre- and Protohistory of the Berach Basin*, Southeast Rajasthan, which was published by Deccan College in 1967. He also participated in the prehistoric exploration in the Narmada valley and in the excavations at the Neolithic site of Tekkalakota in Karnataka and the early site of Tripuri in Madhya Pradesh, all under the leadership of H. D. Sankalia. He also explored sites of enigmatic copper hoards as well as Painted Grey Ware and latter cultures in Hardoi, Farrukhabad, Shahjahanpur, and Kanpur districts.

In 1972, V. S. Wakankar (who discovered the site of Bhimbetka in 1957) and V.N. Misra excavated the site in collaboration with the Deccan College.

In 1977, V.N. Misra collaborated with R. P. Dhir, a well-known pedologist of the Central Arid Zone Research Institute (CAZRI), VNM and D. P. Agrawal of Physical Research Laboratory (PRL) to resume a research in Rajasthan to understand the evolution of the environment of the semiarid and arid region, known as Thar Desert, on the western side of the Aravalli. In addition to survey explorations, the team also excavated many sites, namely, Singhvi Talav, Jayal, Chhajoli, Indola-ki-Dhani, Bangar Canal, and in Didwana Lake. V.N. Mishra has played a major role in the development of archaeological research and studies at Deccan College in Pune. In December, 1991 he organized an international workshop at Deccan College on the introduction of African Cultivars into South Asia. The papers were successfully published by the Indian Society for Prehistoric and Quaternary Studies in 2003, Pune, under the tittle Introduction of *African Crops into South Asia*. V.N. Mishra also played a major role in having Deccan College granted the status of Deemed University in 1994.

In 1982, V.N. Misra with the help of V. C. Joshi, the project officer with the Ford Foundation joined the expedition led by the distinguished archaeologist J. D. Clark for search of early humans in Ethiopia. After that V.N. Misra invited Joshi to visit the Deccan College to meet his colleagues and see the research work being undertaken in archaeology. In 1983, Joshi visited and was highly impressed by the research output and potential of the department. This led to the Ford Foundation providing a grant of nearly 300,000 US dollars to the department for argumentation of research facilities. Later, the foundation awarded four more grants and an amount exceeding 800,000 US dollars in total. These grants were used for the acquisition of sophisticated research equipments such as an X-ray diffractometer,

atomic absorption spectrophotometer, a number of microscopes, several vehicles for field work, books and journals for the library and for the establishment of a computer center.

In 1972, during V.N. Misra's tenure as Director of Deccan College, the University Grants Commission in India recognized the archaeology department of the Institute for its Special Assistance Programme (SAP). In 1985 the status of the department was upgraded to being a Centre of Advanced Study (CAS). The work of the center was evaluated by expert committees in 1992 and 1998. On the basis of these reports the University Grants Commission sanctioned substantial grants to the department for the acquisition of laboratory equipments, books, journals, vehicles and the hiring of secretarial staffs. V.N. Misra also established a Deccan College emergency relief fund for the peons, watchmen, and other categories of employees whose salaries are low. In addition, he played a major role in the Indian Society for Prehistoric and Quaternary Studies in 1975, which was established to promote research in prehistory, quaternary studies, human evolution and ethnoarchaeology.

The society and its journal *Man and Environment*, which was founded in 1977, have been a misson for V.N. Misra. He was instrumental in establishing the H.D Sankalia Memorial Lecture and the H.D. Sankalia Young Archaeologist Award through the society.

V.N. Misra's distinguished international career has spanned five decades. In 1966 he collaborated with L.S. Leshnik of Heidelberg University, West Germany to carry out extensive explorations in Rajasthan and Gujarat mainly to test Leshnik's hypothesis that early agriculture may have begun in the foothill region of the Aravalli Mountains. They discovered two Mesolithic sites namely Tilwara in Barmer district in western Rajasthan and Bagor in Bhilwara district in eastern Rajasthan. V.N. Misra and his colleagues C.G. Padval and Lakshaman Matal from Pune excavated the sites jointly with the Department of Archaeology and Museums of the Rajasthan Government, Jaipur. The Bagor excavation (1968 to 1970), remains the largest Mesolithic site excavated in India and has provided excellent evidence of the process of acculturation in Indian prehistory. In 1969 V.N. Misra participated in the Second International Conference of Asian Archaeology organized by the Sri Lankan Government's Department of Archaeology at Colombo and presented a paper on his work at Bagor. In 1970 he was awarded a Homi Bhabha fellowship to study European prehistory. He gave lectures on Indian prehistory at several places and participated in Francois Bordes' excavation at Pech de I'aze and in Henry de Lumley's excavation at Grotte de Lazaret in France. On completion of the fellowship V.N. Misra prepared a monograph on *Mesolithic Age in India*, which he submitted to the Homi Bhabha Fellowship Council. In 1969 Jack Golson of the Australian National University, Canberra met V.N. Misra. He invited V.N. Misra to present a paper on Indian Microlithic industries at the eight meeting of the Far Eastern Prehistory Association, held in January, 1971 in Canberra, Australia, under the auspices of the 28th International Congress of Orientalists. In 1979 V.N. Misra went to Greece under the auspices of the Indo-Greek cultural exchange programme. During this time he visited many famous archaeological sites and museums and also gave lectures on Indian Archaeology in the Archaeology Department of the University of Athens. In 1983 he was awarded a senior Fulbright Fellowship, which he held during January–May 1984 at the Department of Anthropology, University of California, Berkeley. During his 1962 to 1964 explorations in Mewar, he discovered Balathal, one of the nine sites of the Ahar Chalcolithic culture. From the excavation in this site V.N. Misra revealed that the subsistence economy of the Balathal people consisted of cultivation and the domestication of animals and that the technology mainly consisted of copper tools though occasionally stone blades and microliths were also used. V.N. Misra has participated and presented papers in over 50 national and international conferences, seminars, symposia and workshops.

Mission Archaeology in North America

Lee M. Panich
Department of Anthropology, Santa Clara University, Santa Clara, CA, USA

Introduction

Religious missions have played an important role in colonial programs across the globe, and in North America they were one of the most intense forms of colonialism encountered by indigenous peoples. The archaeological study of missions has followed the same developmental trajectory as research in historical archaeology more generally: from particularistic studies focused on restoration of historic sites to laboratories for building cross-cultural generalizations about culture change and to increasingly collaborative research that furthers our understanding of intercultural entanglement, resistance to colonial domination, and human agency.

Mission archaeology includes research on missions founded by various religious orders representing the colonial interests of several European nations in North America. Significant archaeological work, for example, has been conducted on the interactions between Native Americans and Jesuit missionaries operating as part of the French colonial enterprise (Walthall and Emerson 1992), and archaeological studies of mission contexts are growing alongside interest in the archaeology of colonialism more broadly. Missions established in Spanish colonial territories, particularly those founded by Franciscan missionaries, have attracted the most scholarly attention due to their wide geographic range, long period of operation, and close integration into the broader Spanish Empire. These missions were intended to be the primary means of integrating diverse groups of indigenous peoples into the emerging political and economic order and were a centerpiece of the Spanish colonial strategy in North America.

Definition

Mission archaeology is usually focused on the archaeological study of mission complexes and the activities undertaken therein. Recently, however, this traditional understanding of mission archaeology has been expanded to encompass a broader range of sites as well as the social and cultural implications of missionization (Panich and Schneider 2014). Scholars interested in mission archaeology typically draw on diverse lines of evidence, including material culture, archival documents, and ethnographic data (Graham 1998: 25–26). To best highlight these trends, this entry focuses on the Spanish missions of North

America, which date from the 1560s to the 1840s and stretch from the Atlantic coast of Florida and Georgia across the borderlands to Alta and Baja California.

Key Issues

Mission archaeology today falls under the broader category of the archaeology of colonialism, and it shares many of the same theoretical concerns. In North America, missions were often the first permanent colonial establishments, and their study can inform our understanding of frontier economies, core-periphery relations, and the intersection of religious and secular interests (Van Buren 2010). Yet for most contemporary practitioners, the goal of mission archaeology is to examine the complex social relationships and cultural contacts that occurred at missions and related sites. Colonial missions were specifically designed to convert indigenous peoples not just to Christianity but also to Euro-American lifeways, providing archaeologists with datasets uniquely suited to answer broader questions about colonialism and the ways in which native peoples negotiated its constraints.

Mission Architecture

Across North America, many archaeological projects have focused on discovering and delimiting mission architecture. In the Southeast, researchers have worked to locate colonial mission complexes, none of which survived intact owing to the vagaries of climate, building materials, and other forces (McEwan 1993; Fig. 1). From Central Texas to the Californias, where arid climates and durable building materials facilitated the preservation of colonial architecture, a great deal of research has been conducted to aid the reconstruction of mission sites and their interpretation for the public (Fig. 2). In addition to providing crucial information about the history of occupation of particular sites, projects concerned with mission architecture also have the potential to illuminate more general issues of colonial and indigenous land use.

Continuity and Change

In the second half of the twentieth century, much archaeological research on missions was driven by an interest in acculturation, the cultural modification that occurs as one group adopts the practices and associated material culture of another. As it was employed archaeologically, this framework sought to quantify the amount of culture change that took place among mission neophytes – as baptized native peoples were called – by examining ratios of "Indian" to "European" artifacts. Early acculturation studies at Spanish mission sites were undertaken by James Deetz at Mission La Purísima in California and by Charles Di Peso at Mission San Antonio de Padua de Casas Grandes in Chihuahua, Mexico. Despite their widespread use, particularly in California,

Mission Archaeology in North America, Fig. 2 Mission San Borja, Baja California, Mexico. The stone church and an earlier adobe complex have been stabilized by the Instituto Nacional de Antropología e Historia. (Photo by Lee Panich)

acculturation approaches have fallen out of favor in mission archaeology and the archaeology of colonialism more broadly. This shift stems from the recognition that the material and origin of a particular artifact say little about who used it, how it was used, or the symbolic value that may have been attached to it.

The results of several decades of mission archaeology focused on the issues of change and continuity in indigenous societies suggest that Native Americans did not necessarily abandon all of their traditional practices in favor of those of Euro-American colonizers. In Texas and adjacent portions of northern Mexico, archaeologists found that native peoples living at mission sites continued to employ ceramic and stone tool technologies that were direct extensions of precontact traditions (Hester 1989). Archaeological evidence from California additionally indicates that some native neophytes continued to dwell in traditional structures (Fig. 3) and to engage in some aspects of their hunting and gathering economies as well as other cultural practices such as gambling and contacts with indigenous communities living outside of colonial control (Lightfoot 2005; Panich 2016; Fig. 4).

Resistance and Power

Archaeologists have also sought to understand the issues of power that underpinned the missionary enterprise, which often included forced relocation, burdensome labor regimens, and strict social controls. One interesting pattern at many Southeastern missions, where shifting political alliances both facilitated and hindered missionization, is that indigenous council houses are often part of the formal mission complex, as at Mission San Luis de Talimali. This architectural layout, unique to La Florida, underscores the political accommodations made by the Spanish and their would-be converts (Milanich 1999). In the American Southwest, numerous archaeologists have investigated the Pueblo Revolt of 1680 in which Pueblo peoples launched a broad offensive against the Franciscan mission system that involved not just armed resistance but also more subtle reworking of material culture to symbolize social relationships and identities (Liebmann 2012; Preucel

Mission Archaeology in North America, Fig. 3 Native American housepit excavated near the site of Mission Santa Clara de Asís in California, USA. (Photo by Rebecca Allen)

Mission Archaeology in North America, Fig. 4 Obsidian projectile points recovered from Mission Santa Clara de Asís in California, USA. The obsidian used to make the object was likely obtained from neighboring unmissionized groups. (Photo by Lee Panich)

2002). Across the continent, archaeologists are also looking beyond the mission walls to find evidence of native resistance to missionization, which often took the form of fugitivism, the maintenance of autonomous villages, and strategic alliances among native groups (Panich and Schneider 2014).

The Spanish mission system exacted a very human toll on indigenous peoples throughout North America. Bioarchaeological studies demonstrate how a variety of factors – including relocation to mission sites, increased labor demands, dietary shifts, and introduced diseases – resulted in a general decline in the health of indigenous communities, as well as in broader demographic changes during the colonial period (Larsen 2001). Despite the negative outcomes of missionization, excavations of mission cemeteries can also illuminate the power of mission doctrine and how it was negotiated by missionaries and native peoples alike. At Mission Santa Catalina de Guale in Georgia, more than 400 native individuals interred in the mission cemetery were laid to rest largely in accordance with Christian practices, although the presence of significant quantities of grave goods suggests that the Franciscan friars

Mission Archaeology in North America, Fig. 5 Assorted beads (out of almost 70,000) recovered from the Santa Catalina de Guale cemetery in Georgia, USA. Bead types pictured include Ichetucknee Blue, Seven Oaks Gilded, and several hollow, blown beads. (Photo by Bill Ballenberg, courtesy of David Hurst Thomas)

deviated from Church doctrine to accommodate the practices of local indigenous groups (Thomas 1988; Fig. 5).

Identity

Research into ethnicity and identity, long a concern for mission archaeologists, is undergoing a fundamental shift. Rather than simply measuring the loss of indigenous cultural practices in mission settings, archaeologists are today considering the various ways that native peoples reinterpreted their identities during the colonial period. In California, studies of archival documents and archaeological artifacts such as mission ceramics demonstrate that native peoples reinterpreted individual and group identity, which often coalesced around a particular mission establishment (Lightfoot 2005). In the Southeast, scholars are also examining the creation of new ethnicities at colonial sites. Christopher Stojanowski, for example, employs skeletal evidence from native communities before and after contact with Europeans to understand the process of demographic change and ethnogenesis in the region (Stojanowski 2010). Throughout North America, missionization often involved changes in the practices of everyday life as well as in group structure and social organization. To fully understand the implications of such changes, however, archaeologists are examining them not simply as the result of European domination but also as stemming from the interested actions of indigenous peoples.

Building from the material evidence for the reinterpretation of native identities in the colonial period, some archaeologists are considering the implications of missionary colonialism for native peoples today. Kent Lightfoot and colleagues are exploring this issue in California, where many former mission Indians are not recognized by the federal government as legitimate Native American groups due to the often dramatic demographic changes of the colonial period and the assumed success of the missionary program in converting native peoples to Euro-American lifeways (Lightfoot et al. 2013). Recent findings suggest that the processes of population aggregation and the creation of novel forms of social organization and identity put missionized groups at a political disadvantage compared to other indigenous groups who more closely resembled the ideal anthropological model of California Indians. By exploring the varied ways that the diverse indigenous peoples who were drawn into colonial missions managed to maintain and recreate their identities during the colonial period and its aftermath, archaeologists may find common ground for collaboration with descendant communities seeking governmental and popular recognition.

Future Directions

Mission archaeology has long focused on the impacts of missionization on Native American

groups, but current approaches are examining not just change but also the active persistence of indigenous peoples in mission contexts. Across North America, archaeological research at missions and related sites – increasingly conducted in collaboration with descendant communities – shows that native peoples often maintained settlement patterns, architectural styles, technologies, and/or diets that were distinct from those of Euro-American colonists while simultaneously adopting some aspects of introduced material culture. In many cases, the archaeological evidence can be seen as the conscious reconfiguring of traditional practices given the constraints and opportunities of the colonial period. Future research will help develop non-dichotomous ways of understanding continuity and change that highlight the agency of native people.

Yet archaeological evidence also demonstrates the tragic effects of infectious disease, stringent labor demands, and overcrowding at missions that combined to significantly change the demographic structure of native polities and which continue to reverberate across the continent. As seen in the controversy surrounding the recent canonization of Franciscan missionary Junípero Serra, who founded the Alta California mission chain, mission sites today are seen by many Native Americans and others as monuments to an unjust colonial system (Panich 2016). By revealing material evidence of daily life under missionization, archaeology can contribute to the ongoing public debate about the place of colonial missions in the contemporary landscape. The promise and challenge of mission archaeology in the twenty-first century will be to harness community collaborations and public interest to stimulate conversation about the lives of people who experienced missionization firsthand and who are today still grappling with its continuing legacies.

Missionization and Mission Archaeology in New Zealand and Australia

Angela Middleton
Department of Anthropology and Archaeology, University of Otago, Dunedin, Otago, New Zealand

State of Knowledge and Current Debates

Recent work in the field of mission archaeology in New Zealand and Australia shows that despite often-assumed historical similarities of these geographically close countries, there were two differing histories of colonial and indigenous encounter, leading to different trajectories of missionization.

Missionization was in the vanguard of colonization in New Zealand, where the first Christian, evangelical mission was founded in 1814, preceding formal British annexation in 1840. In Australia the situation was reversed. The first British convicts arrived in New South Wales (NSW) in 1788, but despite earlier efforts, it was not until about 1832 that missions to Aboriginal Australians were properly established (Fig. 1).

New Zealand mission stations were primarily the initiative of individuals and Protestant evangelical organizations such as the Church Missionary Society (CMS) and the Wesleyan Missionary Society (WMS). Missionization in Australia was quite different (Middleton 2008: 10, 2010). "Missions" in Australia included government institutions, sometimes considered carceral, in which indigenous Aboriginals were confined, a central element in Australian Aboriginal policy (Lydon and Ash 2010: 1; Grimshaw and Nelson 2001;

Missionization and Mission Archaeology in New Zealand and Australia, Fig. 1 Map of New Zealand and Australia showing locations of relevant sites

Sutton 2003). This pivotal difference is a factor in the analysis of a two-part typology of mission stations in the New World, the "household" and the "institutional" mission (Middleton 2008: 28–30, 2010).

Grimshaw and Nelson's (2001) analysis of the "civilizing mission" of evangelicals supports the argument for Australian missions as "carceral" institutions. In Victoria as elsewhere in Australia, the congruence of missionary goals and state agendas led to a situation where missions appeared to run almost as prisons. "Missionaries and managers appeared not to be their [inmates'] protagonists but their jailers. Religious and secular staff had acquired a capacity for surveillance, coercion and punishment … few outside Australia ever realised," where a "travesty of Christian humanitarianism" was demonstrated (Grimshaw and Nelson 2001: 297).

More recent approaches however have reconsidered the view of the Australian mission as a repressive regime (Lydon and Ash 2010: 2; Morrison et al. 2015: 98–99; see also Flexner 2014: 59–61). Lydon and Burns (2010: 41; Lydon 2014) consider this approach marginalizes Aboriginal people, perpetuating a "view of the missions as places of acculturation rather than indigenous transformation and cultural renewal," the ruins of the mission seen to mark the disappearance of Aboriginal identity and the advent of a white future. Mission stations, in this case principally government institutions run by Protestant missionaries working as their agents (Grimshaw and Nelson 2001), are now viewed as "homelands," where kinship ties were formed and Indigenous ownership assumed.

Missionization in New Zealand commenced in 1814 with the establishment of the first Church Missionary Society mission at Hohi (Bay of Islands, northern New Zealand), also the first permanent European settlement in the country (Fig. 2). This was the brainchild of Samuel Marsden, chaplain to the British convict settlement, established 1788 at Port Jackson (Sydney). Protestant missions in New Zealand exemplify the "household" mission. These were marginal, fragile establishments based on the model of the Christian household, the missionary family living

Missionization and Mission Archaeology in New Zealand and Australia, Fig. 2 Map of Bay of Islands, New Zealand, showing relevant sites

in a small home, initially dependent on Māori benefactors for protection and food. Māori were not contained within the mission but, from the fortifications (known as *pā*) where they lived, exercised power and control over the mission's inhabitants. Spatial factors also differentiated these two models. "Household" missions were usually surrounded by fences, built to protect mission families and prevent unwanted intrusions by Māori (other than the benefactor tribe); the Māori population lived beyond these walls, the missionary often "itinerating" or traveling to nearby villages to catechize, preach, and Christianize. By contrast, the "institutional" mission usually featured fences constructed to incarcerate Aboriginal Australians. Within such institutions, Aboriginal lives were segregated and regimented and forced child removals began the phenomenon of the "Stolen Generations" (Lydon 2005). Although these were sites of coercion, they also served as "refuges from the effects of invasion" and have become sites "inscribed with new cultures and identities" (Lydon and Ash 2010: 2).

During the twentieth century, anthropologists and historians examined Australian missions and government reserves through the lens of "culture contact" and similar approaches (for examples of this literature in Victoria, see Lydon 2009: 42–66). Mission archaeology itself began in Australia with Birmingham's (1992) seminal work on Wybalenna Station, Flinders Island, where some 100 surviving Tasmanian Aboriginals were moved in 1830. Birmingham's fieldwork was undertaken between 1969 and 1971, the same decade that James Deetz began his work in California. This settlement typifies the Australian situation. Wybalenna was "part of a government segregation initiative to protect white settlers and Indigenous Australians from each other during the European occupation of Aboriginal land" (Birmingham and Wilson 2010: 18). The remnant Aboriginal population was effectively incarcerated on the island (Birmingham 1992). Birmingham (Birmingham and Wilson 2010: 17) used documentary records alongside a "limited salvage excavation" to reconstruct the 15 or so years of Aboriginal occupation at Wybalenna. Investigations revealed the chapel, built in 1837, and the remains of five brick cottages out of a row of an original twenty which had once each housed two Tasmanian couples. One of these was used as the "native issuing store" (Birmingham and Wilson 2010: 21). The cottages opened onto a terrace, which Commander George Robinson referred to as the "Natives' Square" (Birmingham and Wilson 2010: 20). A range of European items, including transfer-printed ceramics, glass, buttons, clay pipes, nails, and other metal, along with indigenous artifacts and faunal remains, was recovered, with the presence of mutton for consumption increasing over time. Other faunal elements included dog and marsupials, both large and small, as the settlement's occupants hunted for food to supplement the rations, especially when these did not arrive.

The deposition of the artifacts suggested that the cottages' inhabitants had taken up domestic practices such as routine sweeping of floors, often out the front doors of houses onto the terrace. Some items suggested rewards or gifts given for co-operating with "Robinson's work-and-reward plan" (Birmingham and Wilson 2010: 23). These included beads, marbles, tobacco, and clay pipes; tobacco apparently played an important role in this reward system and was a habit taken up "to excess." More unusual was the number of glass flakes, used for hair cutting, scarring, and medical purposes, as well as butchering meat. George Robinson's journal details daily events, rations, and goods supplied such as clothing and building materials. He also paid the inhabitants with goods for gardening, fencing, mutton birding, and sheep minding, as well as other work. Robinson established a weekly market where the Tasmanians could exchange or sell goods they had produced, including items such as wallaby skins. Wybalenna had a structure similar to many mission settlements with obligatory church attendance, work, and education programs, carried out with the typical aim of "Christianization and Europeanization" (Birmingham and Wilson 2010: 19). Wybalenna was not a success. The mortality rate was high and the settlement closed in 1847 when the last 47 surviving Tasmanians moved to a new location close to Hobart. Despite a scheme that included punishment and

regimentation, the Tasmanian inmates did not conform to expectations, and their efforts at gardening or sheep tending were unsuccessful. They lamented the loss of their traditional practices, which Robinson had effectively banned, despite promises to the contrary when the settlement was first established. Birmingham and Wilson (2010: 27) note that it was the "non-segregated Islander culture that survived," a population of European sealer men and Aboriginal women, some of whom later returned to Wybalenna and persisted on other islands in Bass strait.

While Birmingham's work at Wybalenna involved liaison with the local community of "Tasmanian islanders" (local residents) in the late 1960s (Birmingham and Wilson 2010: 17), by contrast the Lutheran mission site at Killalpaninna, in the northeast of South Australia near Lake Eyre, was long deserted and remote when research was undertaken there in the 1990s. This mission, which was also a government ration station (supplying tea, sugar, and flour), was established in Dieri country in 1867 and closed in 1914. Birmingham (2000; Birmingham and Wilson 2010) used historical and archaeological data to test a set of theories relating to Aboriginal responses to culture contact at this mission: resistance, creolization, and optimal foraging. GIS was used to carry out an extensive survey of abandoned surface scatters, which formed five distinct groups of campsite areas. No excavation was undertaken. Archaeological methods used in the project consisted of "surface surveying, mapping, quantifying and classifying material culture" from the artifact scatters (Birmingham 2000: 365). Birmingham critiqued the dichotomous "dominance-resistance" concept for lacking a "dynamic dimension," not accounting for change and innovation, and disempowering the indigenous or invaded in this equation, who were transformed into victims. Creolization and optimization theories, by contrast, allow for change and resistance without negative associations. Creolization can account for new, vigorous, hybridized forms of culture and innovative uses of material culture. In the context of the mission, optimization theory viewed the mission (and ration station) as a source of "systematic quarrying and utilization of resources" for the local population (Birmingham 2000: 363). All three of the models were confirmed at the mission, where European goods such as bottle glass and salvaged items were used in new, indigenous ways and the Lutherans themselves recorded the systematic Aboriginal exploitation of mission rations and goods, as well as the traditional Dieri practices which they themselves were destroying. Campsite artifact assemblages demonstrated differential relationships with the mission, depending on distance from the mission structures. The Lutherans dismissed the Dieri deep knowledge of the arid desert environment, in which they had traditionally lived on plant and game, drew strength from the environment through ritual and ceremony, and were part of a large network which exchanged stone, ochre, and pituri (a mixture of leaves and wood ash chewed as a stimulant). Once Dieri people had accepted baptism, they were expected to live within the "mission confines," to attend school, and to train for work as domestic or station servants and were forbidden access to traditional practices and lifestyle (Birmingham and Wilson 2010: 29), in a manner which suggests institutional control and repression. The archaeology of the earliest campsites confirmed this separation from traditional life. As the white settler pastoral economy expanded, Dieri traditional life was abandoned and Killalpaninna was eventually taken over as a cattle station, but the mission teaching in literacy, pastoral, and domestic work had provided new skills to the Dieri people, bringing about the development of "a dynamic new community with transformed skills" (Birmingham and Wilson 2010: 34).

The Moravian mission of Ebenezer, founded in 1859, was one of three established in Victoria in the second half of the nineteenth century and one of the state's six government reserves for Aboriginals (Lydon 2009: 5). In short order, in the year after its foundation, the baptism of Nathanael Pepper was celebrated there as the first Aboriginal conversion to Christianity, a "giant milestone for missionaries" (Lydon 2009: 90). Ebenezer was built on traditional country of the Wergaia-language speakers, on

land of the Wotjobaluk, at the place known by them as "Banji-bunag" or "Bunyut Bunnut," where Jane Lydon carried out a research program, starting in 2003. Lydon (2009: 254–270; Lydon and Burns 2010: 44) began this project with the acknowledgement of the "complicity" of the discipline of archaeology with imperialism, with the ways in which this created distance between Indigenous people and their heritage, and the power dynamics at play, disadvantaging those people. With this in mind, and the need to carry out research under new, decolonizing frameworks, the project at Ebenezer took place in consultation and collaboration with descendants of the Wergaia, represented by the Goolum Goolum Aboriginal Cooperative and the Wotjobaluk Traditional Land Council. The mission (a term Lydon (2009: 5) used interchangeably with "reserve") consisted initially of a complex of mission house, dormitory, kitchen, and other outbuildings such as a school room. By 1871 this had expanded to 33 buildings, including twenty "dwellings of natives," with more under construction (Lydon 2009: 136).

Archaeological investigations of the mission house site recovered an assemblage of familiar nineteenth-century artifacts, representing "systems of European domesticity" and typical of other "contemporary colonial sites across Victoria" (Lydon 2009: 137): slate pencil and tablet fragments, clay pipes, and blue and white transfer-printed ceramics in Willow and Asiatic Pheasant patterns. Familiar clothing was issued to the reserve inmates from the mission store: moleskin trousers, twill shirts, blankets, shoes, straw hats, large quantities of fabric, and more, along with supplies of tea, rice, tobacco, sugar, flour, and soap. The Moravians considered that the "consumption of European material goods" was a fundamental aspect of the measure of the "civilization" Indigenous people. This went hand in hand with their demonstration of the arts of domesticity, the cultivation of the land, and the entire adoption of European culture (Lydon 2009: 131). Important in this process was the realm of the household, where "women's domestic management became proof of missionary success" (Lydon 2009: 13).

This mission, or reserve, was a refuge for the Wergaia people from a hostile settler population; Aboriginal descendants of mission inmates now acknowledge a deep but ambivalent connection to Ebenezer and other similar places. As is the case with other Australian missions, archaeology has become important in recent years in the process of reclaiming such places for their descendent communities. While built heritage such as remaining church structures may appeal to the non-Aboriginal community, Aboriginal focus tends to rest on "the more ephemeral traces of Aboriginal-occupied households" and ancestral graves, with a variety of noninvasive archaeological techniques used to identify the location of formerly lost burials (Lydon and Burns 2010: 43). As one of the Indigenous descendants expressed this relationship, "Ebenezer itself as a building is neither here nor there for me but Ebenzer in my story lines is like my left or right arm, it's quintessential to my whole being . . . it's just part of our story" (quoted in Lydon 2009: 247).

At the northern extreme of the Australian continent, in Queensland, Morrison et al. (2015: 98) have argued that at Weipa mission, on the Cape York Peninsula, neither the "household" nor the "institutional" models apply ("Institution or village," a heading enquires). They suggest "new conceptualisations of mission communities are required . . . to highlight the evident variabilty" in the ways missions operated. The Weipa mission, one of three Moravian missions on the Cape York Peninsula, was established in 1898 on Anathangayth country, but on a reserve declared by the Queensland government. This was a Moravian mission, but established for the Presbyterian Church; while initial missionaries were Moravian, later they were Presbyterian. The site's Anathangayth name is Waypandan, where Morrison and colleagues (2015: 86) carried out collaborative research with community Elders to uncover Weipa's "real history." It only had a short life and was abandoned by 1932 when the settlement shifted. By contrast, the two other Cape York Peninsula Moravian missions, Mapoon and Arukun, continued until the 1960s. The researchers argue that "the emergence of the

social institutions used within the mission, along with the spatial practices of the missionaries, reflect a complex set of exchange relationships between Aboriginal people and missionaries focusing on labor, food and material goods" (Morrison et al. 2015: 86). As at Wybalenna, tobacco formed an important trade item and was sometimes withheld as punishment. These exchange networks were essential to the Moravian enterprise and the survival of the mission.

Morrison and colleagues surveyed 75 hectares of the mission complex, electronically recording archaeological features such as exposures of cultural material, remains of built structures, landscape modifications such as mounds and depressions, and individual artifacts. A large collection of several hundred historical photographs was also used to determine the spatial layout and function of buildings within the complex and to compare the existing landscape with aspects of the historical. Building remains included the church, with "slumped earthen walls" (originally of pise de terre construction), mission house, assistant's cottage, dormitories, and a storehouse – sometimes serving as an "impromptu jail" to incarcerate and punish mission inmates (Morrison et al. 2015: 91). The mission house was of a typical "Queenslander" style, built on high piles and of weatherboard cladding. Girls and boys were housed in separate dormitories located close to the mission house or "manse," and the site was enclosed by a complex of fences. While children were confined to dormitories at night, it appears that during the day, they were free to come and go between the mission and the outer villages where their families lived. "Physical confinement" and imprisonment were also used when children "ran away" or broke the rules, so the boundaries between freedom and restraint appear to have been quite blurred. The "village," consisting of a "long row of bark cottages" adjacent to the mission, as described by a visitor in the early twentieth century, was the frequent object of the historical photographs and was probably the two parallel rows of structural remains identified in the archaeological survey, with mounds at the rear consisting of scatters of cultural remains and midden (Morrison et al. 2015: 93).

After 18 years of labor, at Christmas in 1916, the missionary Brown lamented the lack of converts to Christianity. The mission suffered from drought and disease (malaria) and existed "mostly on government funds" as it could not produce enough food to support itself; "no fish no ducks no nothing" (quoted in Morrison et al. 2015: 87). By 1933 the mission had moved, but Aboriginal people continued to visit Waypandan, and at the time of research, Elders recalled going there as young children, remembering their parents' and grandparents' houses and orchards.

At Weipa, and as Lydon (2014: 233) found at Ebenezer, the spatial layout formed a "didactic landscape" (Morrison et al. 2015: 100), presenting a "normalizing," westernized, and hierarchical model, with "neat rows" of houses and fenced yards. Beyond this lay the village, where Aboriginal inhabitants could overlay "their own spatial practices." The same spatial layout – the row of English style cottages – was found at Wybalenna (above), equally a "didactic landscape" and perhaps typical of the Australian mission setting.

Mary-Jean Sutton's (2003: 78) analysis of 41 of Queensland's approximately 64 Aboriginal institutions found that in twelve of her sample, the use of "locks, wire mesh enclosed verandahs, barred windows, barbed wire fences, strictly regimented spaces and segregated built environments" on missions and government reserves demonstrated the characteristics of Goffman's (1962) "total institution," leading to her finding that many "missions and reserves in Queensland were total institutions and the spatial and physical environment of these institutions was an attempt at social control over Aboriginal peoples" (Sutton 2003: 78). Some missionaries themselves believed that missions functioned in a manner similar to prisons and were places where severe discipline was enforced and punishment meted out. Such institutions segregated the sexes and separated families, sometimes using wire fences and locked doors to demarcate and protect girls' dormitories, but the one key attribute of the total institution was the "division between inmates and staff"' (Sutton 2003:79). Included in this sample were the Weipa, Aurukun, and Mapoon missions, all those on the western Cape York Peninsula.

Some years later, Sutton (2015; Sutton and Colyer 2013) carried out further intensive PhD research at Mapoon, the first Moravian mission on Cape York Peninsula, established in 1891. The Indigenous Tjungundji people occupied it up until 1963, when their removal was enforced by the burning of the settlement. Sutton's (2015: Abstract) work examined the ways in which cultural heritage values are generated, and she explored the relationship between Indigenous and mission families. The "total institution" no longer formed the focus of her research, and Sutton now worked closely with the Mapoon Indigenous community on a "covenantal archaeology." This explored the trauma suffered when the Queensland Government and the Australian Presbyterian Church purposefully destroyed the mission buildings by fire in 1963. The removal of families resulted in deep trauma or "solastalgia" for the mission's former Aboriginal inhabitants and their descendants. Sutton used noninvasive archaeological techniques such as mapping and "counter-mapping," recording cultural heritage sites and adding voices of the former mission inhabitants to this. Sutton argued that "storytelling" and narrative, as told by community elders, is as an essential tool of archaeological practice at Mapoon. Mapoon's spatial layout was similar to other Queensland institutions (Sutton 2003), with surveillance and regulated spaces. While this mission had maintained control over its inhabitants, it was also a place of strong attachment for them (Sutton 2015: 177, 91), as Lydon (2009; Lydon and Burns 2010) had found at Ebenezer. The mission site formed a "cultural landscape of multiple layers and meaning and values" (Sutton 2015: 117), with the mission compound and the Mapoon Mission Cemetery forming a central focus of this. Elders use the remains of mission buildings and the surviving garden layout, including the symbolism of the Moravian missionaries, to evoke memories, forming a syncretic system of "cultural values and Indigenous agency." Both Mapoon people and former missionary families (some of whom have traditional Tjungundji names) share a strong attachment to the former mission compound and in particular the Mapoon Mission Cemetery, which is now acknowledged as an important cultural heritage site. Sutton's (2015: 228) archaeological practice was critical to the Mapoon people, as it renewed their "strong attachments to country," reestablished kinship networks, and helped to heal the solastalgia the Indigenous community experienced. These cultural heritage sites now receive the acknowledgement and preservation that they have long deserved.

The Wellington Valley mission in northern NSW was the first CMS mission in Australia, established in 1832 in the structures of the earlier Wellington Convict Station (Ireland 2010). The "colonial landscape" of the convict and then mission station remains intact, recognizable today. Tracy Ireland's (2010) work revealed the location of the former government, then mission house, military barracks, and a store, as well as other sites beyond what is now the Maynggu Ganai Historic Site, after its purchase by the NSW Government for the National Parks and Wildlife Service. The colonial government transferred the convict station to the CMS with the expectation that this would facilitate the settler acquisition of land and the acculturation of the Indigenous Wiradjuri people to work within the pastoralist industry. This was not successful, and the mission closed in 1842. Here, as well as in other missions, Aboriginal children were forcibly removed from their families and confined along with young women within the mission compound. As at the Ebenezer mission, and in New Zealand's "household" missions, the role of missionary wives within the mission house and domestic sphere played a vital role in modeling a "civilized" Christian ideology within a larger "natural" landscape (Middleton 2013a). Today, the Maynggu Ganai landscape can be read as a significant place in the "local reconciliation process," where both "black and white people together" value the landscape for its entangled cultural past and contested histories (Ireland 2010: 152). Ireland acknowledged these values, which resonate with some of Australia's most important current cultural and political issues, in the conservation plan for the site.

Ireland's examination of Maynggu Ganai Historic Site began with discussion of an 1826

watercolor of the convict station by English artist Augustus Earle, featuring an Australian Aboriginal in the foreground of a colonial landscape (Fig. 3). Later that same year, Earle traveled to the Bay of Islands, New Zealand, where he executed studies of the Hohi mission (Fig. 4; Middleton 2014: 29, 31, 65; Smith et al. 2012; Smith et al. 2014), the Kerikeri mission, the Māori stronghold at Kororareka, and other subjects.

In 1806 the Rev. Samuel Marsden and the Bay of Islands chief, Te Pahi, had a fateful meeting in Sydney, NSW (Middleton 2008, 2014; Smith in press). Te Pahi had travelled there to see aspects of the English convict settlement, news of which had filtered through to him from the ships that anchored close to his home at Te Puna and Rangihoua in Pēwhairangi, the Bay of Islands, and through the few Māori who had ventured beyond New Zealand and back again in those early years of encounter, at the turn of the eighteenth century. Marsden and Te Pahi became firm friends, and Te Pahi inspired Marsden to establish a Christian mission to Pēwhairangi Māori. After delays, including his voyage back to England to get the support of the CMS for this venture, Marsden and his group of three "mechanic missionaries" and their families, along with ticket-of-leave convicts from Sydney (coming as laborers), finally anchored off Rangihoua pā at the very end of 1814. By this time, Te Pahi was dead and his nephew, Ruatara, had taken his place as chief. In turn, the well-travelled Ruatara would die in March 1815, just after Marsden left to return to Parramatta. This mission, located beneath the eye and the auspices of Rangihoua pā and its inhabitants, was not an easy place for the missionaries to live. Tribulations and conflict grew between the mission families themselves; growing food was difficult and rations supplied by the CMS were often short or nonexistent. Māori (Ngāpuhi) demanded guns in exchange for the pork and potatoes that they produced and traded with the shipping, a trade that was (nominally) forbidden to the missionaries, but necessary sometimes to obtain food.

Samuel Marsden never lived in the Bay of Islands, but traveled there seven times, the final time in 1837, not long before his death in 1838. He brought mission recruits with him, establishing new mission stations at Kerikeri (1819), Paihia (1823), and Waimate (1830) in

Missionization and Mission Archaeology in New Zealand and Australia, Fig. 4 The mission station of Hohi to the right of the valley, with Rangihoua pā on the hill rising to the left. Augustus Earle, 1827–1828. National Library of Australia PIC T176 NK12/139

the Bay of Islands, each in turn under the control of a *hapū* and its chief (Middleton 2014).

There were no real conversions of Māori to Christianity until 1830; the CMS missionaries labored in Pēwhairangi and beyond for more than 15 years until the first Māori baptisms took place at Paihia in that year. After that time, conversions grew and there was an increasing demand from Māori to learn and use the new technology, literacy, to achieve new goals. Books, including Māori translations of the Bible and prayer books as these were achieved in the mission translation committee, became highly sought after.

Pēwhairangi, the Bay of Islands, was generally under the *mana whenua* (translated as territorial rights, power from the land, authority over land or territory) of the tribal group known as Ngāpuhi. Ngāpuhi itself was made up of a number of independent *hapū* (the primary political unit in traditional Māori society), but the *hapū* with *mana whenua* at Te Puna, Rangihoua, and Hohi were principally Ngati Torehina (who still maintain this authority today), and Te Hikutu, not part of Ngāpuhi. *Hapū* and tribal relationships were complex, interwoven with marriage alliances and intermittent internecine conflict. Land rights were often interspersed across different areas and seasons, for example, with *hapū* accessing marine resources in the summer months and gardens during spring and autumn or families having particular rights to birding in certain trees.

Ruatara and his people agreed to settle the missionaries on the land then known as Hohi, beneath the pā, but for much of the late nineteenth and twentieth centuries, this name became twisted in European orthography to "Oihi" (Smith et al. 2012: 5), as it appears in most historical literature (e.g., Elder 1932, 1934). Recently, this has been corrected and the site is now formally known once again by its traditional name of Hohi. In 1814, a European visitor who came with Marsden, John Liddiard Nicholas, described Rangihoua pā as the "largest and most populous town in the Bay of Islands" (Middleton 2014: 29). There were between 100 and 200 "huts" or houses, constructed on either side of narrow pathways, with meticulously tended gardens. Courtyards had sheds or outhouses, used for cooking and food storage. Carvings could be seen on some of the enclosures. The house of the chief, where Ruatara then lived with his three wives, was located on the highest part of the village and differed from the rest of the structures only in

being somewhat larger, about 20 ft long, 15 ft wide, and 8 ft high. Stones forming a fireplace were the only domestic goods. The interior was very smoky. Outside, baskets of food filled with fern root, dried fish, shellfish, potatoes, and calabashes of water were suspended from forked sticks driven into the ground. Fish for a winter supply were drying on stages supported by posts about 12 ft from the ground. Nicholas enjoyed meeting Ruatara's family, especially his chief wife, Rahu, an attractive woman with sparkling, animated eyes and a cheerful expression, who had recently given birth to a baby son. Samuel Marsden had brought with him a red gown, a present to Rahu from his own wife in Parramatta. Marsden helped Rahu put this gown on, replacing her "own simple dress of a mat tied around the waist" (Middleton 2014: 30).

Intensive archaeological investigations were carried out at the Hohi mission site over two seasons in 2012 and 2013 (Smith et al. 2012, 2014; Middleton 2014: 27–67; Middleton and Smith 2014), in the lead-up to the bicentenary celebrations of this significant site of nationhood, in December 2014. This project and that at Te Puna were undertaken with the consultation and collaboration of the *hapū*, Ngati Torehina, many of whom live in proximity to these sites at Wharengaere and Kerikeri. New Zealand's legislation requires this consultation (http://www.legislation.govt.nz/act/public/2014/0026/26.0/DLM4005414.html).

The mission was built on a series of terraces cut into a steep hillside, as Augustus Earle's watercolor (Fig. 4) shows. Alongside and above it stood the imposing Rangihoua pā; Samuel Marsden had purposefully established the mission there, despite the missionaries' pleas for Te Puna, a more open and fertile space on the other side of the pā. Hohi was the place where ongoing relationships between Māori and Pākehā were first established and new cultural identities forged. Prior to the mission's foundation, the site was an area of gardening for Māori, as the archaeology demonstrated.

The 2012 season uncovered the remains of a building on the upper terrace. The nature of the artifact assemblage, dominated by slate pencils (MNI of 90, from 142 individual fragments [NISP]), suggested the function of this building. It was the mission school (Figs. 5 and 6) which opened in August 1816 with Thomas Kendall as the school master and five male and nineteen female pupils on that day. Although its pupils numbered around 70 at its high point, the school had a short life and had closed by December 1818 (Smith 2014; Smith et al. 2012), although it was later reestablished in a different building. It depended on supplies of food, clothing, and "gifts" to be given to its attendees to encourage their attendance. When the CMS failed to send Kendall the goods he requested from to keep the school going, attendance dwindled and the school closed. Other artifacts from the school site included children's toys as well as greenstone jewelry – two elegant ear pendants of the kind traditionally worn by Māori. There were no domestic artifacts in this area, also pointing to the building's educational function. The school and Kendall's neighboring house had been sacked by Māori in 1823, as the documentary record described; the mission was periodically subjected to such events, known as *taua muru*, plundering parties, for infringements of cultural norms. The mission's inhabitants had to quickly come to terms with Māori cultural practices, or suffer such consequences.

The archaeological investigations revealed the building methods and dimensions of this and other first-phase mission structures, built directly onto the ground surface using a local timber not suited to lengthy preservation in the humid, damp northern New Zealand weather. The school and other structures uncovered in the 2013 season had been demolished by 1824, replaced with two second-phase mission buildings, using stone bearers to keep the timbers above ground, presumably to reduce the possibility of rot. The two second-phase buildings can be seen on the upper terrace in Fig. 4. Excavations alongside descriptions of the settlement helped to identify the houses of mission families including that of Thomas and Jane Kendall, William and Dinah Hall, and John and Hannah King. After his dismissal from the CMS in 1823 (largely for an adulterous affair with a young Māori woman, the

daughter of a chief of the pā and part of the Kendall household), Thomas Kendall's home and the nearby school where he once taught were demolished and his house buried beneath clay, soil, and rubbish, then covered with a layer of beach pebbles. The stone fireplace over which Jane Kendall had once cooked and where some of her fragmented ceramics lay was well buried below this material. Kendall had long been out of favor with Marsden and with his missionary colleagues for a number of misdemeanors, but particularly for his close political alliance with the Ngāpuhi chief Hongi Hika (Binney 2005). It seems that they had wanted to bury the evidence of his existence at the mission.

By 1828, the Hohi mission was struggling and many of its houses were scarcely inhabitable. In that year, Marsden and the CMS committee agreed to shift the mission to Te Puna, and in 1832 the last missionaries remaining at Hohi, John and Hannah King and James and Harriet Shepherd, moved their families to new houses they had built there. By this time the center of CMS activity had moved across the Bay of Islands to Paihia, established in 1823. James and Harriet Shepherd did not stay long at Te Puna, and by about 1840 this house was abandoned.

Te Puna was located immediately to the west of Rangihoua, not far from Hohi, and remained under the *mana whenua* of the same *hapū*. Although New Zealand historians have written widely on the history of missionaries and missions, and there had been earlier, partial investigations of mission sites associated with extant mission building restoration and services upgrades, the first research-based archaeological investigation took place at Te Puna in 2002 (Middleton 2008, 2014: 206–225). This revealed the remains of the mission house, in particular the cellar, filled with artifacts and debris of the building in which the King family once lived, as they eked out a subsistence livelihood, teaching and attempting to convert Māori to Christianity, trading goods for food and labor with Māori at Rangihoua, and modeling the appropriate Christian standards of domesticity and gender roles to the Māori population from a marginal site of Christian "civilization" (Fig. 7).

The mission house was of weatherboard "frame" with attic rooms and dormer windows on the upper floor. The house had a lean-to kitchen at the west, where there was a fireplace for cooking over an open fire. Beneath the main section of the house, a large cellar formed a storage space, accessed possibly via a trap door and ladder. The cellar had a wooden floor of native timbers, the walls were lined with wooden planks, and it had recessed shelving on one side. Large

Missionization and Mission Archaeology in New Zealand and Australia, Fig. 7 "Case gin" bottles from the Te Puna mission house cellar

hard wood (puriri) posts set into the cellar walls formed foundations for the house itself. Outbuildings lay to the east of the house. At times, up to about 20 people were accommodated there. School was held in part of the house, with Hannah King and her daughters teaching the girls from the pā and John King and his sons teaching boys. As at Hohi, slate pencil and tablet fragments were included in the Te Puna assemblage. Domestic artifacts including irons, thimbles, pins, and buttons were recovered from the cellar; these and the fabrics ordered from the mission store (shown in the mission accounts) attested to the sewing undertaken there and the efforts made to maintain appropriate standards of domesticity and appearance (Middleton 2007a, 2013a). Hannah King's needlework skills were well known, and garments stitched by her, now over 200 years old, as well as samplers by her daughters, are held in museum collections. Food was served on blue and white Staffordshire dinner sets of various patterns popular in the early nineteenth century, some of it the same china, or of the same pattern, that was brought from England and used at Hohi. Fragments of Willow, Wild Rose, Village Church, and Rhine ceramics were recovered at both sites, along with other patterns, and matching vessels are held in collections of the King family. Between ten and twenty people may have sat down to meals – the King family, Māori children and adults staying in the house, sometimes one or two chiefs from the pa, or visitors from other missions or clerics from afar (Sydney or England). Faunal remains showed that, at both sites, pork was often the main meat eaten, with occasional mutton or beef. Rabbits, fowls, and turkeys were also kept for food. Potatoes were regularly purchased from Māori at the pā, as the mission accounts showed (Middleton 2007b). Although not plentiful in the faunal assemblages, fish and shellfish were occasionally eaten, caught, or collected from the adjacent shorelines. Teawares, including elegant "London-style" ceramics, suggested that tea parties may have been part of the Te Puna mission repertoire, although Hannah King was not included in the inner coterie of mission women. These were the accoutrements of a civilized mission station, but life at Te Puna was necessarily frugal and there were no luxury or frivolous items – unless the large number of "alcohol" bottles recovered from the cellar could be considered so.

In 1834, visitors to Te Puna walked from the mission to visit Rangihoua pā. Few people were living there by this time, and it was disused and "out of repair" (Middleton 2014: 218), although the palisading fortification still stood. By this time, Hohi was abandoned and the center of both Māori and mission activity had shifted to the center of Pēwhairangi; to the missions at Kerikeri, Paihia, and Waimate; and to Kororareka, where the shipping, mostly whalers, preferred to anchor to re-water, re-victual, trade, and drink. Rangihoua was no longer the vibrant village it had been in 1814. At Paihia, the CMS mission was built on land under the control of Ngati Hine, although this was a contested place, with neighboring *hapū* equally claiming rights there, as the missionaries would soon find out to their consternation. At length, a Māori village, fenced with the usual palisading, grew up to the south of the mission buildings. Hongi Hika (Thomas Kendall's ally), of the *hapū* Ngai Tawake, purposefully placed the new Kerikeri mission beneath the eye of one of his own strongholds, Kororipo pā, with its village spreading out on a ridge above the mission. Waimate mission, on the land of Ngati Rehia and other *hapū*, was perhaps the only Bay of Islands mission station demonstrating a "civilized" landscape. Charles Darwin certainly considered this the case when he visited the mission in 1835, describing it as something of an English idyll: "the thoroughly English appearance of three well-designed, respectable houses, surrounded by gardens, out-houses, and well-cultivated fields, was surprising and delightful. . .. The farm had 'fine crops of barley and wheat in full ear," potatoes, clover, "large gardens, with every fruit and vegetable which England produces . . . asparagus, kidney beans, cucumbers, rhubarb, apples and pears, peaches, apricots, grapes, olives, gooseberries, currants, hops, gorse for fences and

English oaks!" (Darwin quoted in Middleton 2014: 183). Despite such praise, that bountiful mission farm would soon decline. Waimate too had a "village" where Māori lived adjacent to the mission, as well as at a large pā, Okuratope, nearby.

Other Protestant missions soon expanded down the length of the North Island and into the South Island, finally to the Lutheran mission on Ruapuke Island in Foveaux Strait (Middleton 2013b). Surveys of these and later CMS and WMS sites, along with archaeological, visual, and archival sources, demonstrate a similar spatial and social model of the mission station as that found at Te Puna and Hohi. The typical New Zealand mission station consisted of the missionary husband, wife, and family living in a simple, usually wooden, house, sometimes with a chapel and school associated, where they labored to convert Māori to Christianity and to bring about the cultural transformation of Māori society through the model of Christian daily life and domestic practices.

In New Zealand, as elsewhere across the New World, missionaries were deeply implicated in the processes of colonization. CMS leader Henry Williams (based at Paihia) played a pivotal role in negotiations between Māori and British with his translation (often construed as misleading) of Te Tiriti o Waitangi (the signed version of the Treaty of Waitangi) in 1840. When wars over land and sovereignty broke out, Williams and others trod a tenuous line between government policy and support for Māori, seen as disloyalty to the British (Middleton 2015). There was also the question of missionary purchases of large tracts of Māori land made prior to 1840. Trade and the development of a "spirit of commerce" were important factors in New Zealand from 1814; artifacts from the Te Puna archaeological context, analyzed alongside accounts, demonstrate the role of the mission in trading with Māori (Middleton 2007b) and the advent of capitalism, one of historical archaeology's central themes. In 1814, Māori were active agents in bringing the new institution of the mission into their midst, and they used this as a means to participate in the modern world on their own terms. The slow progress toward the missionary objective of conversion to Christianity can be attributed largely to Māori disinterest. For Ngāpuhi, the missionaries represented a source of foreign goods and, through control of these, a monopoly on power within the Māori world. Only when trade goods were more widely available and the negative outcomes of a more widespread European population became apparent did Māori seek out Christianity in the hope that it would provide access to the knowledge behind European culture (Smith 2014: 626).

A glaring difference between Australia and New Zealand is geography: Australia is a large continent, with huge variations in climate, landscape, and politics, separated into state governments. Within Australia missions varied according to these conditions. By contrast, New Zealand is a small nation of two main islands with much less variation; its nineteenth-century mission stations were more uniform in nature. They were established earlier than missions in Australia, well before colonization. By the time missions and reserves in some regions of Australia, such as Queensland, were beginning to be established in the 1890s, New Zealand missions, and especially those in the Bay of Islands, had long closed. Both kinds of missions differed in their relationships with Indigenous people. In Australia many missions and reserves were seen as places of refuge from a hostile and often violent settler population, where Aboriginals were protected and identity and culture could be renewed. At the same time, missions and reserves were also places in which trauma was experienced and is still recalled today, as Sutton has pointed out is the case at Mapoon. New Zealand missions were not reserves and were not sites of refuge. Rather, missions were established on Māori land by *hapū* and tribal authority for the benefits, such as trade and

access to European goods, they would bring. This included possible access to guns. Māori lived principally outside the bounds of the mission, although some were part of the mission households where they learned domestic skills and provided labor. Those mission sites today are not considered sacred to tribal populations, but rather as having a history shared with missionary descendants and contemporary church bodies.

Spatial layout differed between the case studies described in both countries. The New Zealand "household" mission was small; the Te Puna mission consisted of two family homes, one of which was soon abandoned. The Hohi mission houses appear to have been built in an ad hoc fashion, as needs changed or new personnel arrived. The steep hillside on which the buildings perched created challenges for the occupants, who surrounded their houses with high fences, probably to separate themselves from their neighbors, with whom they were often in dispute, as well as to protect themselves from any unwelcome Māori intrusions. These were not idealized, civilized, or "didactic" landscapes, although they were sometimes represented as such in lithographs and paintings. Māori meanwhile suited themselves, sometimes establishing villages close to the missions, such as at Paihia, or maintaining occupation of their own territories in adjacent pā and *kainga* (villages). However missions across a range of Australian sites, such as those at Wybalenna, Weipa, and Ebenezer, show planned, "civilized," didactic landscapes, demonstrating to their Aboriginal occupants how their lives should be rearranged according to Westernized and Christian ideals.

Despite their differences, whether "household," "institution," or "village," New Zealand and Australian missions shared similarities, in particular the focus on domesticity and the household as a vehicle for bringing about religious, social, and cultural change in Indigenous societies. Indigenous agency meant that this was not necessarily achieved. Māori were selective in the ways they chose aspects of the new culture for their own objectives. At Hohi, the artifact assemblages consisted primarily of "European" objects, but used in an indigenous context, as was the case at Ebenezer (Lydon 2014: 242, 246). Lydon points out that archaeologists cannot use these assemblages to argue for assimilation, acculturation, or "white settler domination" (as was once the case). The social context of such assemblages needs to be taken into account, creating more nuanced understanding of processes, stories, and histories on such complex, entangled "sites of encounter" (Lydon 2014: 233). Mission sites across both countries share archaeological assemblages with similar European artifacts, such as common ceramics, glass, metal, and other items. In all cases, "conversion was also symbolized by monogamy, nuclear family units, the adoption of European material items including styles of dress, a preference for a sedentary existence, and the inclination to work for wages or goods" (Morrison et al. 2015: 85).

In Australia, missions still remain "powerful symbols of home and country" for Aboriginal Australians (Lydon 2014: 234) in a way that could never be the case in New Zealand. There, Māori maintain *mana whenua* over pā and sites of significance, but consider mission sites such as Hohi under the *mana* of missionary descendants, or they may share this *mana* with those descendants.

Mizoguchi, Koji

Akira Matsuda
School of Art History and World Art Studies, University of East Anglia, Norwich, UK

Basic Biographical Information

Koji Mizoguchi was born in 1963 at Kitakyushu City, Fukuoka Prefecture, Japan. He is a Japanese archaeologist who specializes in social archaeology. After being awarded his Ph.D. in archaeology from the University of Cambridge, United Kingdom, in 1995, Professor Mizoguchi became an Associate Professor in archaeology at the Graduate School of Social and Cultural Studies, Kyushu University, Fukuoka, Japan. In 2013, he was promoted to Professor at Kyushu University. From 2000 to 2002, Professor Mizoguchi taught Japanese Archaeology at the Institute of Archaeology, University College London, United Kingdom (Fig. 1).

Mizoguchi, Koji, Fig. 1 Koji Mizoguchi

Major Accomplishments

Professor Mizoguchi has published extensively on Japanese and European archaeology and on archaeological theory. His books *An Archaeological History of Japan: 30.000 BC to AD 700* (2002) and *Archaeology, Society and Identity in Modern Japan* (2006) are considered to be essential reading for anyone studying Japanese archaeology in English. His early work concentrated on the investigation of mortuary practice in the Yayoi period (900–400 BCE to mid-third-century CE) in Japan. He conducted a detailed examination of how mortuary practices informed, and were

informed by, the social structure and material culture of Yayoi societies. After that, his research scope gradually extended to explore the application of advanced archaeological theory and methodology. Often, he built on contemporary sociological and anthropological scholarship, by applying this to an understanding of prehistoric societies in Japan, notably those in the Jomon, Yayoi, and Kofun periods, and also in terms of the historical formation of Japanese national identities.

Professor Mizoguchi's English language publications have made a major contribution towards increasing international understandings of Japanese archaeology. His book *An Archaeological History of Japan: 30.000 BC to AD 700* made a groundbreaking contribution to the integration of traditional archaeological investigation and contemporary critical sociological and anthropological theory. (This encyclopedia includes no entries beginning with Mj–.Mn.) Drawing on reflexive postprocessual theory and further extending it, he critically examined the notion widely shared among the Japanese that a unique culture had existed uninterrupted on the Japanese archipelago since the first human settlements more than 30,000 years ago. His critical and reflexive investigation of Japanese archaeology was developed further in his book *Archaeology, Society and Identity in Modern Japan*, which delves into the role of archaeology in the formation of the modern Japanese nation and explores the process by which archaeological practice is shaped by national social and intellectual discourse.

Professor Mizoguchi is recognized for his contributions to the "internationalization" of Japanese archaeology. Often, outsiders view Japanese archaeology as exotic and yet esoteric. This is due to linguistic barriers and a tendency for Japanese archaeologists to focus on detailed history and chronology at national, regional, and local levels, which are, in part, a product of the meticulous and highly organized recording techniques adopted at every stage of archaeological investigations in Japan. In addition to his publications in English, Professor Mizoguchi has encouraged his students to communicate, present, and publish their research in English and to take part in archaeological excavations, workshops, and conferences abroad.

In 2006, Professor Mizoguchi was awarded the Japan Society for the Promotion of Science Prize in recognition of the contribution that his extensive publications, research, and pedagogy have made to situating Japanese archaeology within a broader framework of world archaeology. In January 2013, he was elected as President of the World Archaeological Congress (WAC) during the Seventh World Archaeological Congress, held at the Dead Sea, Jordan.

Mobiliary Art, Paleolithic

Camille Bourdier
Institut Universitaire de France, Université of Toulouse Jean Jaurès, Toulouse, France

The terms mobiliary/portable art refer to incised, engraved, perforated, carved, or painted remains found at Paleolithic sites from c. 40 to 10 kya. Their ability to be handled, manipulated, and transported is what in essence separates these artistic manifestations from rock and cave art. The term "art" is conventionally used yet must not be accepted in its colloquial and contemporary definition, despite the extraordinary formal qualities and technical mastery of some of these objects, which could be qualified as artistic "masterpieces." Indeed, this category includes a wide range of archeological remains bearing graphic traces, made in a high diversity of materials and media and with variable techniques, motifs, forms, and compositions (Clottes 1990a; Averbouh and Feruglio 2012; Cleyet-Merle et al. 2017). This category of "art" consists of figurines, raw materials (bones, slabs, pebbles, etc.), and personal ornaments, in addition to a variety of tools and items of hunting equipment. It comprises of very different media: transformed or non-transformed blanks, objects of utilitarian and non-utilitarian nature, and sometimes recycled items (waste from subsistence or technical spheres). The size of these objects varies significantly, ranging from minute (pieces that can hardly be held in one's hand) to massive (examples weighing dozens of kilograms that could only have been displaced a few meters at most).

A large variety of organic (bone, ivory, antler, teeth, shell, amber, coral, lignite) and inorganic materials (limestone, sandstone, schist, marl, steatite, calcite, clay) were used, some very common, others more exceptional. Constrained by environmental context, the materials exploited often show deliberate human choice within range of available resources. These choices seem to be embedded both in pragmatic technical reasons, according to the physical properties of the materials, and in cultural considerations, as highlighted by long-distance diffusion of ivory, lignite, amber, or cetacean teeth (Corchón et al. 2008, Cattin 2017). Often the material itself contributes in an active way to the creation of these pieces; the notion of "raw material blank" in this sense is too reductionist. Blank morphology can often contribute to certain anatomical distortions, focus the artist's attention on particular body parts, or constrain the postures represented. This latter case is well exemplified by the turned head of the famous bison licking its flank from La Madeleine (Fig. 1 no. 2). Sometimes this use of an object's natural morphology or features appears so intrinsically linked with the depiction (the example of the famous "pierres figures" comes to mind) that the question can be raised as to whether a symbolic or semantic link exists between material and chosen representation.

A wide range of techniques were used: engraving using fine and superficial or wide and deep incisions, these being obtained via different methods (grooving, scratching), light carving, sculpture in the round, and to a lesser extent drawing and painting. This technical diversity is partly related to the physical properties of the materials. Nevertheless, the rarefied nature of drawing and painting is striking even though taphonomic processes certainly contributed to their rarity. It does however seem that drawing and painting were used less in the production mobiliary art than in rock/cave art during the European Upper Paleolithic. Different techniques were often subtly combined: often fine engraving was used to depict the internal details on carved motifs or sculptures in the round (Fig. 1 no. 1, 2, 5; Fig. 2 no. 4–6), or in other cases, engravings were filled with red or black paint (for instance El Parpalló, Laugerie-Basse, La Vache).

Both figurative and what we perceive as abstract (i.e., nonfigurative) motifs are found on pieces of Upper Paleolithic mobiliary art. Animals largely dominate the figurative domain and

Mobiliary Art, Paleolithic, Fig. 1 (continued)

consist largely of real, i.e., non-imagined, species. Carved or engraved anthropomorphic representations with added animal features, such as the Löwenmensch (Lion man – a human with the head of a cave lion) found at Hohlenstein-Stadel (Germany), or hybrid animal depictions remain rare (Fig. 2 no. 1). Even when selected from reality, the figurative repertoire is not a carbon copy of the exterior world; rather, the attention is drawn to particular subjects. The depiction of plants is rare, and the recognition of landscape features and possible maps is heavily debated (Utrilla et al. 2009). While both are often focused on the animal world, the figurative repertoire manifest on mobiliary art appears more varied than its counterpart found on cave walls. It appears that large and medium herbivores prevail, with horse and bison being the most frequent animals depicted, followed by ibex, the sometimes-indistinguishable deer/doe, reindeer, and ox (Fig. 1 no. 1, 2, 5, 6, 7, 8; Fig. 2 no. 4–6; Fig. 3 no. 2, 3, 6; Fig. 4 no. 1–2; Fig. 5 no. 2–4; Fig. 6). Mammoths and carnivores (felines, bear, fox – Fig. 5 no. 2) can also be represented along with occasional marine mammals (seals, cetaceans), fish, birds, amphibians, and insects. Human representations are relatively abundant at a number of sites, while rare or absent at others (Fig. 2 no. 2, 3, 9; Fig. 3 no. 4; Fig. 5 no. 1). Representations of women or female body parts (pubic triangle, breasts) occur more frequently than do their male counterparts. A special category of female mobiliary art, the so-called Gravettian Venuses (Fig. 2 no. 2), represents the first known tradition of carved human representations to spread across a large territory, covering more than one million km^2. A similar tradition is known in the Upper-Final Magdalenian, whereby engraved or occasionally carved schematic female figures, whose diagnostic female attributes are often omitted leaving only the line of the back and the buttocks (Fig. 2 no. 3), are found at a similar spatial scale (Otte in Clottes 1990b; Delporte 1993). Significant formal variability is also evident in the animals which may appear realistic (Fig. 1 no. 1, 2, 5; Fig. 2 no. 4, 5, 6, 9; Fig. 4 no. 1–2; Fig. 5 no. 2–3; Fig. 6), schematic (Fig. 1 no. 8; Fig. 2 no. 3, 6), or sometimes even exaggerated (Fig. 1 no. 6, 7; Fig. 3 no. 2). Children and juvenile animals are very rare. So are artifacts, representing both domestic and hunting equipments, and other settlement-related elements. Pieces of clothing and personal ornaments are rarely depicted on the bodies, which are more often than not naked. The Gravettian "Venuses" from Central and Eastern Europe, as well as the Middle Magdalenian stone engravings from La Marche, prove as exception to this trend, noticeably with their elaborate hairdresses, belts, bracelets, and necklaces. There are two essential features of this type of iconography on European Upper Paleolithic pieces of mobiliary art. Firstly, human characteristics are secondary relative to other features, and secondly there is a broad absence of anthropogenic features (e.g., habitat structures) on the landscapes represented. Geometric motifs, including simple lines, dots, circles, triangles, chevrons, and more complex patterns also occur (Fig. 1 no. 3–4; Fig. 2 no. 7–8; Fig. 3 no. 1, 5, 7; Fig. 4 no. 3–6). A variety of different typological classifications have been proposed for organizing these so-called signs (Sauvet et al. 1977; Leroi-Gourhan 1982; Sauvet in Clottes 1990b). Simple shapes are diachronic, whereas complex shapes differ in space and time.

Compositions usually combine several motifs. The distribution of motifs tends to be adapted to the shape of the artifact (linear on elongated

Man Estier); 3–5/engraved and painted blocks from Levanzo (P. Graciozi in Graziosi 1973), Dalmeri (G. Dalmeri), and Romanelli (D. Blanc in Graziosi 1973); 6/engraved slab from Sant Gregori (Fullolat in Clottes 1990a); 7/painted slab from El Parpalló (photo V. Villaverde)

pieces, forming a circle on round objects – Fig. 2 no. 9; Fig. 4). Figurative and nonfigurative compositions are often separated which could indicate either different roles within the graphic sphere or a system of semantic/symbolic equivalencies between the two categories of motifs. Narrative scenes are rare (Delporte in Clottes 1990b; Villaverde Bonilla in Clottes 1990b). Within the animal repertoire, special attention seems to have been given the social interactions, noticeably the specific behaviors performed during the rut (male-male competition, male-female courtship displays – Fig. 1 no. 5), though neither mating nor calving is ever depicted. Scenes depicting human-

Mobiliary Art, Paleolithic, Fig. 4 Pieces of personal ornament shared between Asturias and the French Pyrenees during the Middle Magdalenian: 1, 2/*contours découpés* from Enlène (photo R. Bégouën) and La Viña (J. Fortea in Delporte 1990); 3–6/perforated disks from Isturitz (C. Lucas in Lucas 2014), Le Mas d'Azil (M. Chollot in Lucas 2014), La Viña (J. Fortea in Delporte 1990)

Mobiliary Art, Paleolithic, Fig. 5 Middle Magdalenian engraved slabs: human figures (1), and superimposed reindeer and bear depictions (2) from La Marche (L. Pales & M. Tassin de Saint-Péreuse in Bourdier et al. 2017); ibex (3) and bison (4) from Enlène (C. Servelle in Clottes 1990a)

Mobiliary Art, Paleolithic, Fig. 6 Early Azilian engraved aurochs and horses on slabs from Le Rocher de L'Impératrice which show complete preservation of the graphic conventions used during the previous Magdalenian (tracings C. Bourdier, photos N. Naudinot in PLoS ONE 12(3): e0173037. doi:10.1371/journal.pone.0173037)

human (Fig. 5 no. 1) or human-animal interactions are even rarer. Some instances appear to show, for example, women's dances as depicted on engraved slabs from Gönnersdorf (Bosinski et al. 2001), or a meat sharing scene as has been suggested for the renowned pendant from Raymonden, upon which a bison carcass is surrounded by two lines of schematic human figures (Fig. 2 no. 9). Compositions nevertheless appear to be, for the most part, symbolic rather than narrative in nature. Despite biases introduced by the fragmentation of remains, structural analyses of assemblages have demonstrated the existence of certain structuring principles regarding motif compatibility or incompatibility, as well as other rules of association (Sauvet et al. 1977). Compositions do not appear to be random but are rather thought-out and structured compositional wholes.

Techniques and motifs vary according to the type of artifact (Leroi-Gourhan 1982; Delluc in Clottes 1990b). Among functional objects, items with short use-lives such as projectile points and harpoons are usually engraved with simple nonfigurative motifs. Objects that are technologically more elaborate and have longer use-lives (e.g., spear throwers, *bâtons percés*, half-round rods, spatulas, smoothers) often carry more complex compositions combining both nonfigurative and figurative motifs. Spear throwers and *bâtons percés* can be carved into animal or human forms (Fig. 1 no. 1–2). The ends of smoothers can be shaped into fish fins or other various geometric shapes. Engraved compositions can sometimes extend onto the edges of the worked piece (Fig. 1 no. 3–4). In opposition to decorated utilitarian objects, the spheres of the so-called nonutilitarian portable art are those that more often than not bear either human or animal depictions; the "figurines" are exclusively figurative in nature. The best-known examples are the aforementioned "Venus" figurines, yet animals, including herbivores (Vogelherd, Isturitz, Duruthy), carnivores (Geissenklösterle, Pavlov), and birds (Malta), are also depicted (Hahn in Clottes 1990b; Floss in White and Bourrillon 2015 – Fig. 2 no. 1–5). A few examples only portray selected body parts (the head, breasts, genitals, trunk, and thighs), and the degree of elaboration of these features is quite variable. In some cases, it appears that authors invested considerable effort in the reproduction of intricate details, while in other

cases, works appear to have been left deliberately unfinished, as can be seen in select examples from Kostienki (Abramova 1995; Dupuy in Averbouh and Feruglio 2012). Engravings on slabs differ from other mobiliary art categories in that dozens of figurative and nonfigurative depictions, as well as randomly oriented lines, may be superimposed on the same surface; all of which suggests repeated use (Bégouën et Clottes in Clottes 1990a; Rozoy in Clottes 1990a; Sieveking in Clottes 1990b; Delporte and Clottes 1996; Bosinski et al. 2001; Tosello 2003 – Fig. 1 no. 6; Fig. 5). In the sphere of personal ornamentation, modifications of anthropic origin mostly consist only of a perforation or a groove to facilitate suspension. However, fully carved beads and pendants, in some cases decorated with nonfigurative or figurative representations, also exist (Taborin in Clottes 1990b; Fig. 2 no. 7–8; Fig. 4). Shaped beads have rounded and elongated morphologies (bowl-shaped beads, tear-shaped beads, basket-shaped beads, rounded beads, perforated disks, etc.). Pendants consisting of small sculptures, or which employ the natural shape of bones to portray the heads of horses, bison, ibex, or chamois (*contours découpés*), are particularly rare (Delporte and Clottes 1996 – Fig. 2 no. 6; Fig. 4).

Mobiliary "art" is not uniformly distributed in Europe. Most examples are concentrated in a few specific areas (Southwestern France and the Cantabrian region, Southern Germany, Moravia-Czech Republic, and western Russia). Despite difficulties encountered regarding the dating of these objects, the production of mobiliary "art" does not seem stable during the Upper Paleolithic (see below). Mobiliary art is particularly abundant at some sites, with hundreds or even thousands of pieces, yet can be exceedingly rare or absent at others. From Spain to Russia, some Paleolithic sites stand out for the quality and quantity of decorated objects (Corchón Rodriguez 1986; Abramova 1995; Delporte and Clottes 1996; Bosinski et al. 2001; Tosello 2003; Arias Cabal and Ontañon Peredo 2004; Villaverde Bonilla et al. 2012):

- Spectacular bone objects come from Mas-d'Azil, Altamira, El Castillo, El Juyo, Polesini, Paglicci, and La Garma
- Antler objects from La Vache, La Madeleine, Laugerie-Basse, Isturitz, Gourdan, Plantade, Montastruc, Le Morin, Raymonden, Las Caldas, and La Viña
- Ivory objects from Dolni Vestonice, Pavlov, Kostienki, Mezin, Mezerich, Hohle Fels, Vogelherd, Geissenklösterle, and Brassempouy
- Sculptures from Grimaldi, Isturitz, and Duruthy
- Painted and engraved pebbles from Mas d'Azil and Rochedane
- Engraved and/or painted slabs from La Marche, Gönnersdorf, El Parpalló, Enlène, La Paloma, Limeuil, Fontalès, and Bédeilhac

Mobiliary "art" is found in archeological contexts that vary exceptionally in function, both within and between the different chronological phases. Sites appear to be mainly dense occupations (La Madeleine, Laugerie-Basse, Bruniquel, Fontalès, MA, Isturitz, Gourdan, La Vache, Enlène, Gönnersdorf, Pavlov, Dolni Vestonice, Kostienki, Area I of La Garma Lower Gallery, Tito Bustillo area XI, La Garma A), but examples are also documented within small hunting camp-type occupations (Roc-la-Tour, Rocher de L'Impératrice). Occasionally, small assemblages are discovered, removed from the inhabited areas of sites (Las Caldas IXc), and are sometimes associated with other structures of anthropic origin (e.g., pits at El Juyo). Mobiliary "art" and rock "art" are often found in different contexts. The two can be found together, and when this is so, it generally occurs in the context of intense occupation (La Garma Lower Gallery, Mas d'Azil, Roc-aux-Sorciers, Tito Bustillo, salle terminale de Bédeilhac, Labastide, Gargas). Barring exceptional cases of abundant personal ornaments in particularly rich burials (La Madeleine, St Germain la Rivière, Sungir, Labattut), very little mobiliary "art" is known from funerary contexts.

The Late Epigravettian of Northern Italy appears to be an exception to this trend, as burials were frequently covered with decorated rocks (Riparo Tagliente, Riparo Villabruna A).

The Emergence of Graphic Expressions

Both rock and more portable forms of graphic expression appear roughly at 37,000 cal. BP within the first European Upper Paleolithic culture (the Aurignacian) in Northern Italy (Fumane, Broglio and Gurioli 2004), Southwestern France (Blanchard, Castanet, Bourrillon and White in White and Bourrillon 2015), and Southern Germany (Hohlefels, Hohlenstein Stadel, Conard 2009). Few examples of graphic expression are documented in the Mousterian Middle Paleolithic contexts (Henshilwood and D'errico 2011). These examples consist of engraved or pecked nonfigurative motifs, such as cupules, sequential incisions, and notches, for the most part made on the bone or stone (La Ferrassie, Suard, Saint Anne I, Vaufrey, Oldisleben 1, La Quina, Tagliente, Turské Mastale, Temnata, Axlor, Vergisson IV, Bacho Kiro, L'Observatoire, Tata). A few "proto-sculptures" have also been presented (La Roche-Cotard, Tobalga), though to date there is little agreement in regard to their anthropogenic origin or the intentionality of the attributed forms. Ornaments on shell and animal teeth appear in near and during the transition between the Late Middle Paleolithic and the Early Upper Paleolithic, with dozens of discrete and regionally patterned types (e.g., Vanhaeren and D'errico 2006). Recent finds nevertheless suggest the symbolic use of raptor feathers and talons around 50,000 BP and maybe as early as 90,000 BP (Romandini et al. 2014).

The conditions, agents, or reasons for the beginning of graphic expression – whether on artifacts or rock faces – remain subjects of significant debate. This problem is central to the broader issue regarding the emergence and manifestation of symbolism in human evolution, often taken as a core element of humanity relative to other members of the animal kingdom ("homo symbolicus": Henshilwood and D'errico 2011). When did symbolic thinking start to develop? When and how was it first embodied materially? This critical issue in prehistoric archeology revolves in essence around our ability to provide a self-definition of our "modernity" or "humanity" relative to other animal species but also relative to ancestral or cousin human lineages. How unique is humanity?

In Paleolithic Europe, Neanderthal populations show examples of what could be construed as symbolic behavior, most notably through burials. Yet graphic representation on artifacts and ornaments are few, poorly diversified, and mostly quite recent (i.e., the Late Middle Paleolithic). Some have taken this to be the result of the acculturation of Middle Paleolithic Neanderthals by invading Upper Paleolithic *Homo sapiens* (i.e., "Aurignacians"), while others have put forth arguments supporting independent Middle Paleolithic inventions, and still others claim contact between these two populations necessitated new symbolic mechanisms for their sociocultural articulation. Regardless of the ultimate reality of any of these proposed scenarios, two unambiguous facts remain: (1) examples of graphic production increase significantly once *sapiens* is the clear author, and (2) figurative depictions do not become integrated into the artistic repertoire until 37,000 cal. BP (see below). This need for *sapiens* populations to express symbolic thinking through graphic production, and noticeably through depiction, is explained by two divergent theoretical mechanisms (Mellars et al. 2007; Henshilwood and D'errico 2011). For some, this feature is biologically rooted and linked with new cognitive abilities resulting from *sapiens*' novel and therefore inherently superior, brain configuration. For others, the emergence of graphic representation requires a social trigger, in addition to the aforementioned necessary biological substrate. In this second context, complex, dense, and likely extensive social networks embedded

within the Aurignacian cultural adaptation would have necessitated some form of graphic representation to indicate corporate and individual identities. This externalization of social identities, statuses, or positions would have aided in the negotiation of access to resources via social means (White 1982).

Unity and Diversity in European Upper Paleolithic Mobiliary "Art"

While we have discussed the broad commonalities of mobiliary "art," this form of graphic representation also varies through space and time in regard to the media chosen, the techniques employed, and the motifs and forms represented (Clottes 1990a; Abramova 1995; Averbouh and Feruglio 2012; Cleyet-Merle et al. 2017). Mobiliary art develops during the Aurignacian (38,000–33,000 cal. BP) in two major centers of artistic expression (White and Bourrillon 2015). The first center is located in Southwestern Germany (Vogelherd, Geissenklösterle, Hohle Fels) that is characterized by the production of animal (horse, mammoth, felid) and human figurines in ivory, including the unique discovery at Hohlenstein-Stadel of an anthropomorphic carving of a human with a lion's head (Fig. 2 no. 1). The second center is in the Périgord region of Southwestern France and is characterized by the presence of geometric marks (notches and cupules) on osseous artifacts (e.g., Lartet, Blanchard) and a high frequency of sexual representations (e.g., the sculpted phallus from Blanchard) (Fig. 1 no. 3). These motifs were also deeply pecked on freestanding blocks within occupations (Castanet, Blanchard, Belcayre), together with very schematic animals (felid, horse, ibex, bovin, rhino, mammoth).

Concomitant with the emergence of the Gravettian (33,000–24,000 cal. BP) come the first major expressions of mobiliary art during the European Paleolithic, which occur in three main areas. The oldest and most significant collection of material is located in Moravia, followed by Southwestern France and, more recently, the Ukraine. The famous lozenge-shaped female figurines displaying hypertrophic sexual attributes are known over a vast geographic space extending from France to Russia (Brassempouy, Lespugue, Grimaldi, Willendorf, Dolni Vestonice, Pavlov, Kostienki, Avdeevo, Gagarino) (Fig. 2 no. 2). This continent-wide distribution underlines a profound ideological feature that seems to be shared across different cultural groups and leads us to question both the origin and possible diffusion of this symbol (Delporte 1993). In the Pavlovian and Kostienki cultures of Central and Eastern Europe, bodies show more detail (features, hands, personal ornamentation) and coexist with a second, slenderer female morphotype (Abramova 1995; Dupuy in in Averbouh and Feruglio 2012; Gavrilov in Averbouh and Feruglio 2012). A spectacular and significantly geometric repertoire on osseous materials (Fig. 1 no. 4; Fig. 2 no. 7) develops alongside terracotta figurines (Dolni Vestonice, Predmost, Pavlov, Petrkovice, Wachtberg, Vela Spila) of women and animals (mammoth, felines, bear, wolf, birds) in certain areas. This last technical development does not seem to have spread outside Central Europe and is neither retained by the following archeological cultures. While present, mobiliary art is however less abundant in Southwestern France (El Parpalló, Isturitz, Labattut, Gargas, Pataud) and consists mainly of engraved stones with expressionist style animals (bison, mammoth, horse, aurochs) (Foucher and Foucher in Cleyet-Merle et al. 2017; Rivero and Garate in Cleyet-Merle et al. 2017; Fig. 1 no. 6, 8).

While examples of mobiliary art become more rarefied during the Solutrean, consisting of engraved stones on a handful of sites (El Parpalló, Rochefort), mobiliary art becomes quite common following the LGM, with the most famous images of European Upper Paleolithic decorated items belonging to the Magdalenian (Corchón Rodriguez 1986; Tosello 2003; Arias Cabal and Ontañon Peredo 2004; Rivero in Averbouh and Feruglio 2012; Rivero 2015; Lucas in Averbouh and Feruglio 2012; Lucas in

Cleyet-Merle et al. 2017; Pigeaud and Hinguant in Cleyet-Merle et al. 2017). During the Middle Magdalenian of Western and Central Europe (18,500–16,000 cal. BP), we observe an unprecedented diversification of mobiliary art, with the development of ornamentation on utilitarian items, from the domestic (*bâtons percés*, smoothers) to the cynegetic (spear throwers, projectile points, half-round rods; Fig. 1 no. 1–2). Many new pendant morphotypes also appear at this moment, including the famous *contours découpés* of herbivore heads (Fig. 2 no. 6; Fig. 4), as well as perforated disks (Fig. 4). Some sites also contain significant series of engraved stones (Enlène, La Marche, Bédeilhac, La Paloma, Tito Bustillo – Fig. 5). Figurative depictions dramatically increase during the Middle Magdalenian, together with narrative compositions showing the interaction between several subjects (Fig. 2 no. 9; Fig. 5 no. 1). Figurative and nonfigurative motifs become more numerous but the animals represented are not particularly diverse (horse, bison, ibex, deer). Motifs, forms, and technical processes are highly standardized. Motifs and compositions differ according to the medium used: spear throwers are carved to resemble horse heads (Fig. 1 no. 1), *bâtons percés* are sculpted to resemble bison heads or engraved with sexual motifs, hatched sinuous lines or engraved bison heads are observed on smoothers, and series of engraved V or carved tuberosities in vertical rows on projectile points are among the most typical objects (Feruglio et Averbouh in Cleyet-Merle et al. 2017). Depictions of animals are characterized by a trend toward realism with well-proportioned and complete outlines that are full of internal details, with reproductions of the sensorial organs, the coat, and the osseous reliefs, all in a stereotypical manner (Laugerie-Basse, La Madeleine, Mas-d'Azil, Bédeilhac, Altamira; Fig. 1 no. 1–2; Fig. 2 no. 4–6; Fig. 4; Fig. 5). While the aforementioned characters show strong unity, regional particularities appear in the motifs, conventions, or compositions. To cite a few examples: the "foal and bird" sculpture on spear throwers and the engraved curls on half-round rods in the Northern Pyrenees, the recurrence of realistic human depictions in the Poitou region (Fig. 5 no. 1), or the smoothers carved into fish fins in the Périgord-Quercy area (Delporte and Clottes 1996; Fuentes 2013). During the same period, mobiliary art in Eastern Europe (Mezin-Meziric culture), focusing on geometrics, contrasts significantly with regional traditions in France. This Eastern European variant consists of largely nonfigurative compositions with specific patterns of broken lines or meanders engraved on ivory "bracelets," and this same family of motifs is found in settlements painted in red on mammoth bones. In the figurative sphere, depictions concern near exclusively the female form, with two dominant morphotypes. Both are geometric in nature, lack heads, arms, and legs and emphasize the central part of the body. While one morphotype shows a triangular shape in profile, representing the buttocks, the other is seen from the front with a thin waist and wide hips.

The schematic nature of Upper-Final Magdalenian mobiliary art (16,000–14,000 cal. BP) stands out across Southwestern France and Central Europe and is best illustrated by the so-called "Schematic Feminine Figure" morphotype, which also evokes the Mezin-Meziric feminine profiles – mainly sculpted as figurines or pendants with varying degrees of simplification (Le Courbet, Lalinde, Andernach, Nebra, Petersfeld, Ölknitz – Fig. 2 no. 3). Although detailed figures do exist (Fig. 1 no. 5), animal depiction is also mostly characterized by simplified lines, including the novel representations of front-facing ibex and macrocephalic horses on projectile points and *bâtons percés* (Limeuil, La Madeleine, Gourdan, Mas d'Azil, El Valle – Fig. 2 no. 8). Both aurochs and reindeer become more commonly depicted during this period, and a special new attention seems to be given to bird and fish forms, effectively increasing the overall diversity of animals depicted.

Examples of mobiliary art become increasingly rare on the ground by the end of the Late Glacial (the Azilian of France, Spain, and Switzerland; the *Federmesser gruppen* of Central and Northern Europe), and we see a radical change

around 13,500–13,000 cal. BP. At this moment seemingly impractical media are chosen (pebbles, small slabs, bones) and engraved and/or red painted geometric compositions consisting of repetitive simple motifs, such as points, lines, crosses, and chevrons (Mas-d'Azil, Murat, Rochedane, Los Azules I; Fig. 3 no. 1), together with very rare schematic animal depictions (Couraud 1985; d'Errico 1994; Naudinot et al. 2017), become the norm. During the last Late Pleistocene traditions in Southwestern France ("Laborian"), we see the revival of very expressive animal depictions on the bone, in which very fine engravings of horses and aurochs bear geometric features, and especially filled bodies using hatch marks, grids, and sinuous lines (Paillet and Man-Estier 2014; Fig. 3 no. 2).

Relative to earlier periods and its Magdalenian contemporaries, Epigravettian (18,000–11,000 cal. BP) mobiliary art from the Italian peninsula and the Spanish Mediterranean coast is both less frequent and less well documented (Martini 2010; Astuti and Grifoni Cremonesi in Averbouh and Feruglio 2012; Villaverde Bonilla et al. 2012). Examples include mostly stone (slabs, pebbles) and bone blanks, most often engraved, and otherwise painted red (Fig. 3 no. 4). Consisting of both figurative and nonfigurative motifs, pieces show a general change in techniques, motifs, and forms similar to the trend identified in the Upper-Final Magdalenian and in the Azilian but with regional specificities. A diversity of animals is represented (snakes, birds, hare) with aurochs, horse, and cervids dominating. Human depiction remains rare in terms of relative frequency, yet it appears to become more important as exemplified by the schematic forward-facing human with outstretched arms (Dalmeri, Cervi) found in several sites (Fig. 3 no. 4). Beginning in the Late Epigravettian (16,000 cal. BP), animal representations become schematic, often depict movement, and subjects are far less detailed and often have hypertrophic trunks (Fig. 3 no. 3). In the Italian peninsula, two regional stylistic groups emerge. In Northern and Central Italy, the schematic nature of the lines is emphasized by the technical choice to depict flat figures filled in with red paint. The high frequency of ibex is another regional characteristic. The engravings from Southern Italy bear particular formal conventions that define the "Mediterranean province" developed during the 1970s: stiffer outlines, the filling in of bodies with geometric patterns, and a particular treatment of aurochs' horns (Graziosi 1973). In Mediterranean Spain, animal depictions are also schematic, but features are represented geometrically, which appears to be a regional specificity (Fig. 3 no. 6). Bodies are elongated and often have a triangular forward pointing shape, with small heads, while sensorial organs are reproduced with simple lines. The bodies also remained unfilled. During the Late Epigravettian, the nonfigurative register overcomes the figurative. Very elaborate compositions are created with repetitive patterns, including straight lines in series, as well as some new motifs: rectangles and triangles, multiple waved lines, scalariforms, and "Greek keys" (Cavallo, Romanelli, Paglicci, Parabita; Fig. 3 no. 5). Traditionally classified as nonfigurative, the so-called "ramiforms" strongly evoke leaves or branches (Villabruna A, Dalmeri, Polesini, El Parpalló – Fig. 3 no. 7) and could mark the introduction of plants into the iconographic sphere of hunter-gatherer groups during this time.

Meaning and Motivation

Numerous interpretations for both mobiliary and cave art during the Paleolithic have been offered, most of which have come under fire for one reason or another:

- For animal depictions: art for art's sake or hunting and fertility magic (E. Piette, H. Breuil)
- For female representations: fertility rites (H. Bégouën, J.-P. Duhard), ancestor cults or feminine deities, the representation of priestesses (A.P. Okladnikov, E. Saccassyn Della Santa, S.N. Zamiatnine), or the celebration of feminity (P. Rice, H. Delporte, P. P. Efimenko)
- For nonfigurative compositions: simple ornamentation (L. Tchikalenko; R. de Saint-Périer, G. H. Luquet, I. Barandiaran), personal markings (A. Leroi-Gourhan, J. Jelinek), systems of information exchange (S. Mithen, M. Conkey), and ritual markings (A. Marshack)

Structuralist interpretations (A. Leroi-Gourhan, G. Sauvet) have considered both geometric and figurative motifs as elements of a symbolic system depicting cosmological myths, revealing therefore ontological features of these societies. According to Leroi-Gourhan (1982), male-female dualism should be at the heart of all symbolic systems as he considers it to be an underlying structural element to all societies. Beginning in the 1980s, researchers became less interested in ultimate meaning, to many considered an unachievable goal, and rather shifted toward mobiliary art's function, the possible social roles these items and their graphic systems may have filled in past societies, and the motivations for graphic reproduction, all spheres being explored via different methodological approaches (technological, structuralist, contextual). This multiplication of research themes and methods is the reflection of a realization that the extremely variable media, motifs, and assemblages encountered in contexts of mobiliary art, spanning over vast geographical spaces and time depths, are likely not explainable by a single general characteristic.

Ritualistic Interpretations

There has traditionally been a hermeneutic division made between utilitarian objects used in daily life and nonutilitarian items, thought to have been created and used in religious/ritual contexts. Such an interpretation is based on figurines that were repeatedly engraved, covered with signs, which are sometimes erased, and patinas suggesting significant manipulation or the deliberate breaking of pieces. The discovery of Gravettian figurines in pits located inside or close to habitations has also been used to support the ritual hypothesis (Kostienki 1-I, Nebra, Avdeevo) (Fig. 2 no. 2). The sharpened legs on some Gravettian Venuses (Grimaldi, Savignano, Tursac, Malta) have also been used to argue that they were inserted into the ground for permanent display. Alternative interpretations have nevertheless been proposed for the broken objects. Recent technological analyses indicated that breakage on the Kostienki 1-I figurines could have resulted from accidents during manufacture (Dupuy in Averbouh and Feruglio 2012). In much the same way, the so-called ritualistic breaking of Magdalenian engraved slabs remains difficult to demonstrate. While intentional breakage is well attested at sites such as Gönnersdorf, La Marche, Limeuil, and La Madeleine, where pieces of slabs were recycled in fireplaces and/or paving floors (Fig. 5), and this breakage is often interpreted as the ritualistic destruction and scattering of the stones (Tosello 2003), it remains impossible to demonstrate the contemporaneity of the engraving and the fracturing events. This could simply be an example or secondary recycling of previously symbolic object into a utilitarian sphere, and this alternative hypothesis is supported by the fact that some depictions made on pieces had already broken.

Paleolithic Notation Systems

A. Marshack (1989), among others, conducted microscopic analyses of Paleolithic objects bearing sequences of notches, incisions, and punctures, and subsequently interpreted these as being notational systems, counting devices, or, in some instances, lunar calendars (Fig. 1 no. 3). This interpretation was based on the number of marks present on the objects and the identification of morphological variations in the marks themselves, taken to be representative of different tools. The idea of multiple tools is subsequently used to argue that various marks were added at different moments in order to record items or events. Alternative interpretations have been proposed by F. d'Errico (1994) and others based on experiments identifying different tools, showing that in a number of cases Marshack's interpretations were either (1) unsupported by the evidence or (2) that, while still best interpreted as notations, they likely differ from the systems proposed by Marshack.

Mobiliary "Art," Social Networks, and Territorial Structuring

Considering graphic expressions as a medium for information exchange to negotiate social identities, various interpretations have focused on information exchange theory (Wobst 1977; Wiessner 1983) to correlate Paleolithic mobiliary art production with socioeconomic systems and infer

community patterns (Conkey 1980; Bahn 1984; Schwendler 2005). The spatial distribution of morphotypes, motifs, forms, and/or technical processes is used to reconstruct social networks and territorial structuring (broad vs reduced; open vs closed). If single or few "exotic" morphotypes could illustrate exchanges, common formal, and technological norms revealed by techno-stylistic analyses would therefore represent more closely shared systems and thus imply regular meetings, cooperation, and partnerships between social formations. It appears therefore that very connected long-distance networks seem to develop during the Middle Magdalenian, notably between the Aquitaine and Poland (Fuentes et al. in Bourdier et al. 2017; Kozlowski et al. in Bourdier et al. 2017; Maier in Bourdier et al. 2017) and between the Northern Pyrenees and the Asturias (Corchón Rodriguez 1986; Fritz et al. 2007; Arias Cabal and Ontañon Peredo 2004; Rivero in Averbouh and Feruglio 2012; Lucas in Cleyet-Merle et al. 2017; Fig. 4). In contrast, the very specific trend to represent humans with detailed features in the Poitou, as opposed to schematic or grotesque depiction elsewhere, is seen as a mechanism of social affirmation and differentiation (Fuentes 2013; Fig. 5 no. 1).

The agents, processes, and even directions of these social dynamics are difficult to treat; do they represent direct or indirect connections, and what is the frequency and nature of these relationships (the movement of objects, individuals or families, or whole bands)? Sites with high concentrations of the most conventional mobiliary art are considered as workshops dedicated to the production of a single or a few specific item(s) for diffusion in other local or regional satellite sites, such as the projectile points and *bâtons percés* with engraved macrocephalic horses at La Madeleine during the Upper Magdalenian (Apellaniz in Clottes 1990b; Fig. 1 no. 7), or the *bâtons percés* with engraved bison heads at Isturitz during the Middle Magdalenian (Rivero 2016). Larger diffusional distances are taken to indicate increased sociocultural influence of respective sites. Since the pioneering work of M. Conkey (1980) and P. Bahn (1984), there has been a growing interest in investigating the social function of the mobiliary "art" sites, assuming they must have played critical roles for structuring social articulatory mechanisms between individuals and bands (Delporte and Clottes 1996; Rivero 2016). With regard to other archeological data (accommodation capacity of the site, thickness and number of archeological layers, diversity of activities performed, investment in the spatial structuring of the place, presence of "exotic" items and eventually of rock art), sites with high concentration of pieces are taken to characterize either base camps or aggregation sites where affiliated of bands gather. A high variety of motifs and graphic compositions with the association of elements found at other local sites and original features may differentiate the second from the first (Conkey 1980), an interpretation that has notably been put forward for the Middle Magdalenian sites of Altamira, Isturitz and Mas d'Azil, and the Pavlovian site of Pavlov I (Svoboda in Averbouh and Feruglio 2012).

Mobiliary "Art" and Social Organization

Beginning in the late 1980s, investigation into the author(s) of "decorated" items has become a central issue in exploring the social function of graphic and plastic production. Studies of form and technological analysis look into the social identity of the makers (Apellaniz in Clottes 1990b; D'errico 1994; Fritz 1999; Rivero in Averbouh and Feruglio 2012; Rivero 2016). Technical processes and sequences of movements (orientation, pressure, direction, chronology) allow analysts to recognize to recognize "signatures" and to characterize their degree of knowledge and practical know-how. In some archeological cultures, it appears that the production of mobiliary "art" was conducted by experts with a significant degree of technical know-how and profound knowledge of aesthetic conventions (Late Aurignacian in Swabian Jura, Pavlovian, Kostenkian, Middle and Upper Magdalenian). The possibility of specialization leads to questions regarding the role of these items in the economic sphere and the respective social organization of

their users/producers (prestige/division, competition/collaboration/regulation) and more broadly questions pertaining to the division labor in these societies. In others contexts, production may have been more common, meaning that techniques and forms/motifs were more easily learned and could have been reproduced by anybody, such as the Azilian painted and engraved pebbles with simple markings and geometric motifs (Naudinot et al. 2017). This dichotomy between expert and regular production could point to the changing social roles of mobiliary "art" throughout the Upper Paleolithic, yet the simplicity of techniques and forms does not necessarily mean nonspecialized production, as such elements are culturally conditioned.

In addition to identifying pieces having been worked by experts, technological analyses have also yielded evidence of novice and apprentice work (Fritz 1999; Rivero 2016), i.e., different stages within the theoretical and practical process of apprenticeship. According to degrees of technical and formal control, engraved slabs have been interpreted as either experts' sketches prior to realization on another medium (La Marche: Fig. 5 no. 1–2) or as "training blanks" for novices and apprentices (Enlène, Limeuil: Fig. 5 no. 3–4; Bégouën and Clottes in Clottes 1990a; Tosello 2003). This last interpretation has also been proposed for osseous materials showing little transformation (butchery waste, osseous industry waste, or recycled objects: Aurière in Averbouh and Feruglio 2012). The practical conditions (places, media, tools) of apprenticeship still need to be determined, while the organization of the learning process in terms of duration, number, age of individuals concerned, and mobility of the experts is more difficult to access. Finally, the stereotyped learning pathways seem to indicate to the reproduction of cultural techno-stylistic conventions. This reproduction is sometimes highly standardized, such as the case of the Middle Magdalenian where strong social control seems to have conditioned much of the graphic production. Such evidence of control is taken to reflect denser social networks and more complex social relations and perhaps even their large-scale institutionalization (Fritz 1999; Rivero in averbouh and Feruglio 2012). Other archeological cultures seem to have less strict conventions where individual liberty of creation appears to be authorized.

Some Future Perspectives

Considering the many issues faced when investigating mobiliary "art," as well as the diversity of research trends see over the last decades, a few questions stand out as necessitating particular attention moving forward. At the scale of artifacts themselves, it is first and foremost necessary to reconsider the archeological relevance of our modern classification systems: what exactly are we looking at when we question this vast and polymorphic category, dubbed mobiliary "art"? For instance, are notches on bones to be considered ornamental or could notation systems or technical by-products of certain modes of production be at play? Studies on the relationships between media and their respective graphic compositions must be further explored to remedy this situation. Within the family of objects made on osseous materials, was the selection of the material (animal, bone) random or intentional? Is there a connection between the species used as media and those depicted (Bosinski in Cleyet-Merle et al. 2017)? What can be inferred on a symbolic/interpretive level? To provide new insights into the origins, motivation, and meaning of marks and motifs, the sphere of activities in which items were involved and eventually their status (exceptional or ordinary) must be investigated, especially with regard whether items were actually used (Lucas in Cleyet-Merle et al. 2017). Taphonomic studies (D'errico and Villa 1997) have become critical to make progress regarding questions of ritual breaking and the intentional movement of some examples (slabs, figurines). For a better understanding of artifact life histories, systematic technological analysis must be used to determine whether production was segmented in

space and time and how objects were introduced into, transported from, or abandoned at sites. More generally, investigations into temporal dynamics would surely provide novel information pertaining to the sociocultural functions of mobiliary "art" and its production in societies where short-lived artifacts co-occur with objects having long use-lives and significant patinas and/or traces of repair (e.g., the repaired Montastruc mammoth-shaped spear-thrower). In technological, use-wear, and taphonomic types of analysis, the use of 3D technologies should be standard practice in attempting to accurately characterize the transformation processes of pieces at all steps of the *chaîne opératoire*, from raw material and blank selection to graphic production itself, as well as the use, reuse, and eventual discard of the objects themselves.

The hypothetical reception of these works is another critical topic which deserves more investigation. As examples of visual creation, every motif on pieces is made for an audience, whose number (individual, small group, large group) and nature (human/nonhuman, age, gender) can be extremely variable. The diversity of sites in which mobiliary "art" is documented as well as the different scales of distribution of these items (local, regional, supra-regional) obviously encompasses several contexts of reception and social uses (individual, band, inter-band). Yet addressing this issue of audience and user in regard to mobiliary "art" requires the detailed examination of their archeological context, i.e., the frequency and intensity of the occupation (stratigraphic sequence) and the nature of the activities performed in situ (artifacts, structures, marks), as has been attempted by researchers applying information exchange theory. Strategies of perception have received much less attention yet could provide other clues regarding questions of audience, the choice of "what" to communicate is not disconnected from the questions of "who" is the target, and "when" and "how" to transmit said information. It is clear that some decorated Paleolithic items were made to be seen, exhibited, exchanged, and moved, whereas others were not meant to be seen or removed from sight, whether by being hidden or destroyed. Analyzing the visibility and legibility of the objects and their graphic compositions would appear to be a particularly promising avenue in regard to these questions, yet requires some methodological advances, both in terms of tools used and analytical criteria evaluated.

When investigating the social use and meaning of mobiliary "art" in the European Upper Paleolithic, its relation with rock/cave art remains an essential topic of research, all the more so as a spatial dichotomy seems to characterize their respective locational organizations – does the fact that they are rarely found together extend to the symbolic and/or social spheres? To date, studies have focused on similarities in motifs and forms in order to develop chrono-cultural typologies of rock/cave art. A broader comparative approach that moves beyond simple time-space archeological systematics and toward audience and social function/value has yet to be conducted. Possible complementarities between these two realms of "art" remain to be explored, and their relationship settlement patterns are perhaps the most interesting future avenue of research on this theme.

It is also essential to seriously consider to continuity and change in graphic traditions during the Upper Paleolithic. Mobiliary "art" lags behind in regard to dating, especially in comparison with the significant progress made in dating rock art over last 20 years. The lack of precision in the chrono-cultural attribution of many artifacts, including some of the more classic forms – mainly the result of their older contexts of excavation – makes it all the more necessary to develop targeted absolute dating programs. Beyond directly assessing temporal shifts, placing mobiliary "art" within its cultural context would help to comparatively rethink the rhythms of change seen within different spheres of the material culture (technological, subsistence, economic, symbolic). Traditionally presented as synchronous, these evolutions and interconnections appear to be more complicated, with some instances of clear temporal

discrepancies between technical and symbolic shifts having been highlighted by new data (Naudinot et al. 2017; Fig. 6). The identification of internal evolutionary processes acting on mobiliary "art" production remains at the heart of research questions. How does the interplay between different evolutionary processes influence the origins and intensity of mobiliary "art" production and its content (in regard to stylistic continuity or rupture)? The complex relationships between mobiliary "art" production, socioeconomic systems, and their environment need to be integrated into such chrono-cultural lines of questioning. How and to what degree are changes in mobiliary "art" production reflections of greater social and economic responses to shifting climatic conditions?

All these issues require a holistic approach to mobiliary "art" with regard to its economic, social, cultural, and environmental contexts. Analyses should be conducted at several scales, from site level to general areas of influence. Like other archeological remains, mobiliary "art" must be studied as part of an interdisciplinary framework, linking different spheres of activity within prehistoric hunter-gatherer populations (subsistence, technological, symbolic, social) and exploring the role of environmental conditions in their variability. While progress has not ceased since the 1990s, the contextual approach to mobiliary "art" described here must become standard practice. Finally, these interdisciplinary approaches must also delve into other fields of human research (anthropology, ethnology, cognitive psychology) as to broaden our conceptual and methodological perspectives regarding the roles and uses of graphic production in the hunter-gatherer societies.

Moche, Geography and Culture of

Luis Armando Muro Ynoñán
Lima, Peru
Department of Anthropology, Stanford University, Stanford, CA, USA

State of Knowledge and Current Debates

Time and Space

The Moche (also known as "Mochicas") were a pre-Hispanic society that developed on the desert north coast of Peru between the second and ninth centuries AD. The Moche did not develop a writing system (logographic or syllabic). They created, instead, a highly elaborated artistic record that was used as media to encode and diffuse complex symbolic messages. The refined and standardized Moche art was expressed in a variety of material mediums: murals, textiles, ceramics, and metals (Fig. 1), and has been recognized by many as one of the most remarkable art styles of the pre-Columbian Americas.

Although still controversial, Moche is considered by many as the first civilization in the Andes to attain state-level social complexity, judging by their massive adobe constructions distributed along the north coast of Peru. Its recognition as one of the first pristine states of the New World is grounded on the identification of urban features in major Moche centers that show significant political and social centrality, planning, hierarchy, and craft specialization (Fig. 2).

Discussions of the incipient development of the Moche must first consider their successful adaptation to the harsh environment that characterized the north coast of Peru in the first millennium. Geographically located between the Pacific Ocean and the western mountains of the South American Andes, the north coast is a narrow desert strip containing small rivers and oases naturally characterized by their low agricultural productivity. The natural scarcity of both water and permanent land resources has historically converted this region into a hostile and rough area for human occupation. Nonetheless, and paradoxically, early groups settled in the region as early as BC 4000 (Bird 1948). The confluence of

two maritime currents, the "Humboldt" cold water current and "El Nino" hot water current, established conditions for the development of one of the richest and most varied maritime ecosystems in the world. Maritime resources, combined with efficient strategies of land resource exploitation, created suitable conditions for the incipient development of pristine civilizations (Moseley 1975).

The abundance of maritime resources contained in the equatorial Pacific Ocean strongly contrasts with the periodical destruction and devastation caused by "ENSOs" (El Niño-Southern Oscillations). ENSO is defined as a drastic oscillation in the ocean-atmosphere system produced by unusually warm ocean temperatures in the equatorial Pacific. This annual phenomenon that takes place at the end of the year is frequently accompanied by severe rainfall that potentially causes destructive flooding and, subsequently, drastic droughts in the Peruvian coast. Evidence of severe El Niño phenomena has been registered on the Peruvian coast as early as 3000 BP (Sandweiss et al. 2007).

Far from constituting a threat, the mitigation of the effects caused by the El Niño phenomenon turned into opportunities for ancient Peruvian populations. It seems further evident that particularities of human agency, when stimulated by environmental stress, trigger drastic transformations that alter the economic, political, and cultural structures of human groups. In this sense, the strategies of hazard management created by the ancient coastal populations of northern Peru are considered the basis for the successful environmental adaptation in the region. The way in which El Niño impacted these populations, as well as the range of historically contingent and socially constructed options for mitigating it, sets the conditions for the emergence of "charismatic leaders" that progressively accumulate economic, political, and religious power (Billman and Huckleberry 2009).

Before the Moche appear in the archaeological record of the Peruvian north coast, many other human groups settled and successfully adapted to the hostile conditions of this part of the Central Andes: the Cupisnique, the Salinar, and the Gallinazo or Virú. Four thousand years of accumulation of knowledge, technologies, and processes of adaptation crystallized in a unique society characterized by its sociopolitical complexity, its monumental and massive constructions, and its incredibly elaborated craft technology.

Reaching a relatively homogenous consensus of what Moche was and when and how this phenomenon emerged is not simple. Throughout more than 100 years of development of Moche archaeology, a great variety of theoretical models and paradigms have been developed and proposed not only to understand the tangible manifestation of this phenomenon – its material culture – but also the complex social, political, and economic dynamics that gave it shape in a quite specific space and time.

Uncommon in Peruvian archaeology, most of what we know about the Moche people is based on data principally recovered from long-term excavation programs conducted in northern Peru. Many of them were initiated in the early 1990s and are now led by Peruvian archaeologists in collaboration with public and private institutions: the Sipán Project, led by Walter Alva; the San José de Moro Archaeological Program, led by Luis Jaime Castillo; the Huacas de Moche Project, led by Santiago Uceda and Ricardo Morales; and the El Brujo Project, led by Régulo Franco. Many of these projects have been pivotal not only in advancing our understanding about the Moche people but also in revaluing the Moche identity of contemporaneous traditional populations Likewise, these projects are very important in rescuing Moche sites seriously threatened by human destructions. Other projects conducted by foreign and Peruvian archaeologists have also been pivotal in shedding light on the emergence, development, and collapse of the Moche in different valleys along the north coast of Peru: from south to north, Milosz Giersz, Patrycja Przadka, and Krzystof Makowski in the Huarmey and Culebras Valley; Tom and Sheila Pozorski in the Casma Valley; Donald Proulx and Duccio Bonavia in the Nepeña Valley; David Wilson and Claude Chapdelaine in the Santa Valley; Gordon Willey and Jean-Francois Millaire in the Virú Valley; Garth Bawden, Brian Billman, and Gregory Lockard in the Moche Valley; Glenn Russel, Jeffrey Quilter, and Michelle Koons in the Chicama Valley; Christopher Donnan, Tom Dillehay, Edward Swenson, Marco Rosas, and Ilana Johnson in the Jequetepeque Valley; Steve Bourget in the Zaña and Virú Valleys; Carlos Wester and Manuel Curo in La Leche Valley; Izumi Shimada in the Chancay-Lambayeque Valley; and, finally, Krzystof Makowski and Peter Kaulicke in the Piura Valley (see Fig. 2).

Based on other published reviews and current state of the art of the investigation of the Moche, I will divide this article in six sections that broadly synthetize what we currently know about this enigmatic society: (1) Origins; (2) Chronology and Models of Geopolitical Organization; (3) Art, Warfare, and Ritual; (4) Death and Ancestrality; (5) Monumentality and Urbanism; and, finally, (6) Collapse. The fourth section touches upon topics that I have been exploring since 2013 based upon my own investigations at the monumental area of the San Jose de Moro site in the Jequetepeque Valley.

Origins

The study of the origins of the Moche has occupied and still occupies a prominent position within Moche archaeology. Despite the fact that this topic represented an underlying concern since the times of the first Moche scholars (Max Uhle, Rafael Larco, and Gordon Willey), there is still very little consensus about this matter.

Larco, one of the fathers of Moche archaeology, argued that the origin of the Moche state could have been intimately linked to the successful implementation of a highly complex irrigation system in the valleys of the north coast. This process might have occurred around AD 300 (Larco 1945; Willey 1953). According to Larco, irrigation canals created new forms of wealth and, along with that, unpredicted opportunities of political control and accumulation of goods. With these newfound sources of economic power, the first Moche leaders would have been able to finance the creation of centralized and hierarchical political organizations that materialized in the construction of large-scale monuments. It follows that the control of these monuments was essential for the dissemination of ideological messages since these monuments constituted receptacles for the orchestration of public rituals (Billman 2002: 394). Under this perspective, the control of rituals would have been essential since they allowed leaders to have power over the means of ideological production (DeMarrais et al. 1996). Despite that this process, as described by Larco, appears to be obvious for the rise of the first Moche leaders, it has also been relatively accepted that the circumstances in which Moche political power emerged varied according with the particular historical trajectories of each valley of the north coast.

Billman (2002, 2010) takes Larco's argument further. In investigating the origins of the Moche ruling elite in the Moche Valley, Billman argues that the managerial requirements of irrigation systems were relatively unimportant to the emergence of the Moche state in the Moche Valley. Based on regional surveys, he identifies that large-scale irrigation systems were already essential for pre-Moche groups (Cupisnique, Salinar, and Gallinazo). Nonetheless, none of these groups attained the technological advancements achieved during Moche times. Billman holds that highland-coastal interactions and, very importantly, the political control of irrigation systems (all conditions present from AD 300), along with warfare, created the conditions that allowed Moche leaders to form political units that were highly centralized as well as territorial and expansive. It is likely that intensive armed conflict provided the real opportunities for leaders to exert both coercive and ideological power in such a highly fragmented political reality (Billman 2002: 390).

Both Larco's and Billman's hypotheses are challenged by Kaulicke who states that the scenarios presented might not be applicable for the northern valleys of the Moche territory (Kaulicke 1992) (see Fig. 2). Kaulicke moves away from interpretations based on the development of agrarian systems by instead highlighting the social processes involved in the reinvention of ceramic technology. Based on the presence of a significant amount of ceramics associated with the Early Moche style in the Piura Valley (the furthest northern frontier of the Moche territory), Kaulicke suggests that the crystallization of the Moche style corresponded to a complex technological re-elaboration that occurred based on the mixture of preexisting Formative traditions and cultures. Furthermore, taking the funerary evidence as a starting point, Kaulicke argues that the social process that led to the development of the Moche style occurred in the northern valleys of the Moche territory, instead of the southern part of this territory, as Larco and Willey had traditionally argued.

Although Moche scholars have traditionally used unilineal and evolutionary models to explain the origin of the Moche state (Larco 1945), it appears that multiple conditions and factors were involved in the development of this incipient state. Castillo and Uceda (2008) argue that the rise of the Moche could have happened, contradictory to original hypotheses, in several different locations, at different moments, and under different historical contingencies (Castillo and Uceda 2008: 7). The concept of "harmonization" is used by Castillo and Uceda to explain how, under this apparent multiplicity of origins, the Moche groups were tied by elite integrating ritual practices that were generalized among different communities. In this context, ideology, along with strategic

social relations, played a pivotal role in the process of cultural harmonization and homogenization (Castillo and Uceda 2008: 7). Ideology, they say, could have constituted the most important source and strategy of power in the Moche world. They propose that ideological control could allow Moche elite groups to legitimize their economic privileges and social status and, thus, guarantee the access to power as a sacred right. In the same way that ideology could have been instrumental for Moche elite groups to keep and legitimize power, it was also fundamental in their own collapse. It has been convincingly argued that a failure of the ideological control, combined with unexpected and foreign factors, led the Moche to their imminent disappearance (Bawden 1995; Castillo 2010; Castillo and Uceda 2008; Shimada 1994). We will readdress this point in the section "Collapse".

Chronology and Models of Geopolitical Organization

The geopolitical organization of the Moche has been perhaps the most developed, yet controversial, topic within Moche archaeology. The evolution of the ideas regarding how the Moche were politically organized has certainly followed the ups and down of the varied theoretical trends of the key investigators of the Moche culture. The question of whether or not Moche was a state-level society has been and is still implicit in any research on the Moche. Principal trends can be framed within the three classical paradigms: (a) unified state, (b) dual state or multivalley state, and (c) no statehood.

Moche as a Unique Centralized and Unified State

The ideas of the Moche as a unitarian and highly centralized state were mainly developed by and inherited from Larco (1945, 1948). Larco not only published extensively about different aspects of the life of the ancient Moche people but also established the first chronological framework for the north coast of Peru. The basis for Larco's chronology (from Moche I to Moche V phase) was the subtle changes he recognized in the shapes of Moche stirrup-spout bottles from the Chicama and Moche valleys. Based on the wide and homogeneous distribution of these vessels from Chicama to Nepeña (see Fig. 2), Larco conceptualized the Moche as a centralized political entity, with a capital located in the site of Huacas de Moche, in the Moche Valley, from where influence and political control disseminated (Castillo and Quilter 2010: 5). This assertion represented, in fact, the first ever articulated idea referring to the Moche society as a whole.

In 1946, the Virú Valley Project, the first large-scale and multisite project in South America, conducted large excavations in several pre- and post-Moche sites in the Virú Valley in northern Peru. While this project introduced innovative and sophisticated methodologies for studying settlement patterns and the stylistic evolution of ceramic, many of its interpretations gave further support to Larco's concept of the centralized and unilineal evolution of the Moche (or "Huancaco phase," according to Willey (1953)). Discoveries made at both Huaca de la Cruz (Strong 1947) and Huancaco (Willey 1953), major Moche sites in the Virú Valley, were interpreted as tangible manifestations of steady campaigns of conquest launched by the Moche state to control valley resources and local populations (Gallinazo) north and southward.

A few decades later, the Moche-Chan Chan Project, under the initial direction of Michael Moseley (1992), carried out an intensive investigation in diverse sites of the Moche Valley. Although the project's work was mainly focused on the Chimú capital of Chan Chan, great emphasis was also put on studying the administrative and religious functions of Huaca del Sol and Huaca de la Luna. Moseley also supported the paradigm of the unified and conquering Moche state that spread its power up and down the north coast. Furthermore, the distinctiveness of the Moche ceramic style would have represented the "hallmark" of a corporate and state style whose production and distribution were tightly controlled by ruling elite. The distribution of these official paraphernalia espoused the dissemination of a dominant ideology contained in the images depicted on the material culture (Castillo and Quilter 2010; Quilter 2002: 159).

It is worth emphasizing here the role that iconographical studies played in the development of

the paradigm of a unitary and expansionist Moche state. Moche narrative art was unquestionably interpreted as an orthodox expression of a state artistic program (Benson 1972; Donnan 1976; Hocquenghem 1987). Iconographic studies did not question the interpretations of the political nature of the Moche organization (Quilter and Koons 2012: 25). They confirmed, rather, that Moche art was the expression of a corporate state art highly controlled both in production and distribution (Donnan 2010). Likewise, the reoccurring patterns of Moche ceremonial centers and their large-scale artistic programs supported, the idea of an imperial growth through military conquest (Fig. 3). Moche art as a whole was interpreted, thus, as an expression of religious symbolism whose dissemination was evidently promoted by state political interests.

These concepts allowed the first Moche scholars to construct a model of the rise and development of a single Moche state whose expansion started by AD 200 and was only stopped by external invasion and natural disasters occurring around AD 600. Invasions and natural disasters would have triggered the weakness of the elite's authority as well as a profound social instability in the Moche society which finally languished by the end of the Early Intermediate Period (see section "Collapse" for further details on the Moche collapse).

Moche as a Dual State or Multivalley State

In 1960 a significant number of very atypical Moche ceramics were found at the site of Vicús, Piura Valley, located 400 km north of the well-known Moche core comprised of the Chicama-Nepeña Valleys. The assemblage discovered in Piura was composed of well-elaborated Moche ceramics along with specimens belonging to the early ceramic traditions of Virú and Salinar (Kaulicke 1992; Makowski 1994). The so-called Vicús phenomenon challenged, for the first time, Larco's five-phase ceramic sequence and its scope of applicability. In this setting, the ideas

Moche, Geography and Culture of, Fig. 3 Polychrome friezes decorating the northern façade of the Moche temple of Huaca de La Luna (Moche Valley). (Photo courtesy of Luis Jaime Castillo B)

about Moche origin were also put under scrutiny. Castillo and Quilter assert "the Vicús abnormality could, by no means, be explained under Larco's centralized and political unified paradigm since, for Larco, the origin of the Moche style would have only been circumscribed to the Moche valley from which it spread" (Castillo and Quilter 2010: 11). This "abnormality" was harder to explain after the discovery of a set of royal tombs in the site of Loma Negra, also located in the Piura Valley (Makowski 1994). The subsequent discovery of other royal tombs in the early 1980s, both in La Mina in the Jequetepeque Valley (Narváez 1994) and in Sipán in the Lambayeque Valley (Alva 1988), made much more evident the gaps and limitations of Larco's chronology as well as its scope of applicability. Royal Moche families ruled the northern valleys of the Moche territory as early as their counterparts in the southern valleys. As stated above Kaulicke (1992) argued, that the origin of the Moche style would have been more associated with socio-technological phenomena occurring near modern Ecuador rather than in the Peruvian Moche-Chicama Valleys.

In 1994, Castillo and Donnan consolidated the idea of a dual Moche state. This alternative model visualized two Moche regions that coexisted relatively independent of each other: the "Southern Moche State" and the "Northern Moche State." The first state consisted of the already-known Moche core comprised of the Chicama, Moche, Virú, Chao, Santa, and Nepeña Valleys, which were incorporated by military conquest. In this territory, Larco's sequence generally holds (Castillo and Donnan 1994; Quilter 2002: 160). The Northern State included the Valleys of Jequetepeque, Lambayeque, and Piura and had a three-phased ceramic sequence, Early, Middle, and Late, different from the Southern Moche State. Although this model was primarily developed for the Jequetepeque Valley (Castillo and Donnan 1994; Castillo 2001, 2010), the idea of two Moche entities coexisting was largely supported by significant differences not only in ceramic traditions but also in funerary practices, architectural styles, and metallurgic technologies.

The idea of a dual Moche political organization was further problematic since it could explain neither the high variability in the ceramic styles present in the "Northern Moche State" nor social phenomena involved in their production (Quilter and Koons 2012; Koons and Alex 2014). Investigations led by Shimada in Pampa Grande (Lambayeque Valley), Bawden in Galindo (Moche Valley), Castillo in San José de Moro (Jequetepeque Valley), and Dillehay in various other sites in the Jequetepeque Valley provided new insights on the fluctuating, rather than static, dynamics of the Moche political organization. Greater attention was drawn to the historical and cultural particularities that triggered specific social developments, not only within each valley but also within every single site. Thus greater emphasis was put on resistance over domination, historical particularities over cultural process, agency over structure, and heterarchy over hierarchy. This trend was especially useful in the study of settlements and ceremonial centers associated with the political collapse of the Moche, which started to be intensively investigated in the 1990s (see section "Collapse").

By drawing attention to the decentralized settlement patterns in the Jequetepeque, Zaña, and Lambayeque Valleys during the Late Moche period (circa 600–800 AD), Dillehay (2001) analyzed the Moche communities in the countryside as well as their cultural responses to both political disturbance and environmental stress. He argued that Moche hinterland communities, independent of crisis situations in large Moche centers, adapted their own social organization and intercommunity relationships through shifts in their domestic and political economies. This led him to conclude that a heterarchical model of political organization, rather than a hierarchical one, can better elucidate the social dynamics within a fragmentary political landscape as seen in the Jequetepeque, Lambayeque, and Zaña Valleys in Late Moche times.

Castillo uses the notion of "heterarchical power relations" to propose his political model of "opportunistic states" (Castillo 2010). Unlike Dillehay, Castillo argues that the scenario of political balkanization in the Jequetepeque Valley took place during the Middle Moche (circa AD

400–600) and was sustained by complex and redundant irrigations systems (Castillo 2010: 83). The division of the valley into territorial units was both a cause and consequence of factionalism and confrontation among the polities. However, what made this situation a real contradiction was the high level of political integration that occurred under specific circumstances such as the celebration of large-scale rituals, the construction and maintenance of irrigations canals, and the defense against external political threat. In other words, "an ever-fluctuating political organization that turned into either an integrated or disintegrated political system depending on the opportunities and/or threats in the system" (Castillo 2010: 106). Under this paradigm, Moche statehood was neither inevitable nor stable; hence, centralization and consolidation was more opportunistic than structured.

No Paradigm, No Statehood

Quilter and Koons (2012) carried out a critical evaluation of data that allowed scholars to consolidate the notion of Moche statehood. By criticizing historical-materialistic and normative approaches, Quilter and Koons hold that the idea of Moche as a state-level entity was actually never supported by the archaeological data. They reject, therefore, the models of Moche as a single, unitary, expansionist or multivalley state. These models, based on an *a priori* search for traits and signatures of statehood revalidate, they say, neo-evolutionist approaches, which are no longer tenable given the evidence (Quilter and Koons 2012: 128). Hence, a Moche state, north, south, or altogether, is not supportable.

For Quilter and Koons, the critical issue for a better understanding of the material record associated with the Moche is not whether it was or was not a state, since definitions of statehood are always crafted by neo-evolutionist criteria that force the data into models. They, instead, argue in favor of "a closer examination of how economic and political power was distributed, marshaled, and employed within specific spatio-temporal boundaries" (Quilter and Koons 2012: 136). Since the Moche have traditionally been defined as a phenomenon of accumulated economic power (Billman 2010), we should, they say, assume that political economies varied considerably through time and space. Such a perspective they argue that can lead us to a richer understanding of the Moche and other archaeological cultures in the Andes, which were characterized by fluctuating politics and economies (Quilter and Koons 2012: 136).

They further demand a deeper analysis of the role of religion and politics in the process of making social identities within the Moche world (Quilter and Koons 2012: 37). By figuring out the ways in which religion and politics organized and interpenetrated juxtaposed each other, new insights can be gained on the multiple mechanisms of social conjunction and disjunction that were triggered under specific historical circumstances.

Other scholars have also stepped forward to further deconstruct the notion of a homogenous Moche state. Koons and Alex (2014) re-evaluate Moche political dynamics and inter-site affiliations through the application of Bayesian models onto radiocarbon dates associated with diagnostic ceramic styles. By moving away from the pervasive ideas that equate Moche ceramics with temporal phases, they argue that each valley, or region, used its own local style of ceramics that was within the understood framework of an overall aesthetic tradition: the Moche (Koons and Alex 2014: 1051). This idea has an important implication regarding the political dynamics that occurred in the north coast during the third and the tenth centuries AD, since, under this new dilemma, "aberrations" in the ceramic patterns would indicate that people were in communication and affiliated through marriage, kin, politics, religion, and other means (Koons and Alex 2014: 33). The patterns of variability do not suggest overt state control or conquest but, rather, demonstrate that the political landscape was complex and changing through time.

Art, Warfare, and Ritual

Art

Doubtless, Moche narrative art has constituted one of the most important sources of information

for studying Moche cosmology and cosmogony. The pioneering and seminal studies of Christopher Donnan (1976), Elizabeth Benson (1972), and Anne Marie Hocquenghem (1987), among others, set the basis for exploring, from an iconographic standpoint, aspects such as politics, religion, ritual, warfare, sex, and death (Bourget 2006) in the Moche world. Two methodological and interpretative approaches can be mentioned regarding the study of Moche art: the "thematic approach" and the "narrative approach."

The "thematic approach" was first developed by Donnan (1975, 1976). It is grounded on the idea that, like Western art, the iconographic characters, figures, and elements of the Moche art group are related through specific and consistent patterns of combination, i.e., themes. According to Donnan, "specific figures can be identified by noting the range of activities in which she/he is engaged, and the consistent setting in which he/she is represented" (Donnan, 1976: 8). Donnan, thus, argues that although Moche art gives the impression of representing an infinite variety of activities, it is, in reality, limited to the representation of a small number of easily recognized activities/themes, e.g., "The Sacrifice Theme," "The Burial Theme," "The Presentation Theme," "The Raft Theme," and "The Revolt of the Objects," among others (Donnan and McClelland 1979) (Fig. 4).

The "narrative approach" of Moche iconography, which opposes yet at the same time complements the previous approach, considers the themes to be, in reality, segments of a larger narrative upon which the Moche myths can be revealed (Hocquenghem 1987; Makowski 2004; Quilter 1997) (Fig. 5). These myths were the basis of the greater part of Moche art (Quilter 1997: 121). Quilter, one of the main advocates of this approach, holds that Moche myths are not necessarily depicted as a whole but rather evoked through particular elements or symbols. Hocquenghem (1987) furthers the argument by establishing links and continuities between Moche myths and those from the early historic period.

In doing so, she incorporates ethnohistorical and ethnographic accounts in order to reconstruct the temporal framework of the celebration of Moche rituals (Hocquenghem 1987; Quilter 1997).

Despite providing crucial information on the Moche people, iconographic studies of Moche art were principally based on museum collections. The fact that these studies suffered from a lack of provenience and context became an apparent problem. This deficiency, however, began to be overcome in 1987, when, due to the Sipán discovery, iconographic studies started to articulate with contextual archaeological information. The incredible resemblance between the garments

Moche, Geography and Culture of, Fig. 4 Scene of human sacrifices depicted on an elite Moche vessel. (Taken from Donnan and McClelland 1999)

and ornaments of Moche deities depicted in the iconography and those found, for instance, within the royal tombs of Sipán (Alva and Donnan 1993) and elite tombs of San José de Moro (Donnan and Castillo 1992) demonstrated, for the first time, the veracity and historicity of the depicted actions (see section "Royal and Elite Burials, Death, and Ancestors" for greater details about Moche elite burials). It became apparent that Moche elite individuals were not only actors in the "Sacrificial Ceremony" (or "The Presentation Theme") but also they were buried by personifying divine characters of the Moche pantheon (Figs. 6 and 7).

As many have argued, the enactment of the well-known "Sacrifice Ceremony" could have constituted a unifying religious element that provided cohesion to all Moche polities over time and space (Castillo and Uceda 2008; Chapdelaine 2011; Donnan 2010). Elements associated with this scene have been recovered throughout all the Moche territory: from the monumental walls at the Moche ceremonial centers of Pañamarca (Nepeña Valley), Huaca de La Luna (Moche Valley), and Huaca Cao Viejo (Chicama Valley) to the ritual paraphernalia recovered at funerary centers such as San José de Moro (Jequetepeque Valley) and Sipán (Lambayeque Valley).

Warfare and Human Sacrifices

Another dimension where the Moche iconography has convincingly converged with the archaeological data is the study of warfare, conflict, and ritual. Moche iconography depicts graphic and vivid scenes of intrapersonal conflict, violence, and human sacrifice carried out in both mundane and extramundane locations (Fig. 8). Scenes of combat between Moche warriors have attracted, from very early on, the attention of scholars. Ferocious combats seem to have occurred at the public plazas of large-scale ceremonial centers being witnessed by hundreds, if not thousands, of spectators. As the iconographic evidence suggests,

combats were likely executed to capture victims for human sacrifices. The defeated warriors were stripped of their combat garments. Then, they walked naked through processions before the huaca, the gods, and the priests. Finally, they were sacrificed in bloody ways; the objective was to obtain their blood to be presented to the priests and gods (Castillo 2000a).

Scenes of ritual sacrifice depicted on Moche stirrup-spout bottles remained in the realm of imagination until 2001 when Bourget (2001) discovered the largest collection of human sacrifice ever found in the Moche territory. Bourget excavated 27 sacrificed individuals in Plazas 3A and 3C from Huaca de la Luna as part of at least 5 sacrificial episodes from which 2 were directly associated with the El Niño phenomenon. This evidence suggested a well-organized and systematic ritual system that constituted the basis of Moche religion and ideology.

Until the discovery of the victims of human sacrifice at Huaca de la Luna, the iconographical evidence of interpersonal violence was interpreted as proof of endemic warfare in the Moche world. The sacrificial victims found at Huaca de la Luna demonstrated, on the contrary, that this violence was more associated with magical-religious practices of a sacred nature. This affirmation had already been adverted by Donnan (1975) and Alva and Donnan (1993) who noticed that the iconography does not display real evidence of battles against foreigners. Rather, all the characters in the iconography look like Moche and not foreigner warriors. This fact made Donnan conclude that, in reality, the objective of the battles was not to kill the opponents but to incapacitate them. This argument is further reinforced by the fact that the nature of war objects (clubs and shields) represented in the iconography and excavated archaeologically would be too fragile for real combat. It does not mean that real Moche warfare did not exist, but what is represented in the art is a ritual warfare, as Donnan (1975) states, a true "warrior and death cult."

The argument in favor of ritual warfare is further supported by bioarchaeological evidence. Sacrificial victims not only show wounds made by knives and clubs but also of dismembering and de-fleshing. Body parts (jaws, genitals, and limbs) were removed and apparently scattered through the sacrificial space; in the same way, the face and body skin were partially or totally de-fleshed in order to create "flexed and extended" bodies (Verano 2001, 2008). These treatments of the victim's bodies have been considered by some as ways of sacralizing the existence and corporality of Moche warriors (Hill 2005).

The case of the sacrificial victims found at Plazas 3A and 3C from Huaca de la Luna has led Moche scholars to the discussion about of the biological origins of the sacrificial victims. In this regard, Richard Sutter's and Rosa Cortez's study of bio-distance has provided interesting insights to reassess the arguments against Moche ritual warfare (Sutter and Cortez 2005). Based on the differences of the dental traits, they determine that sacrificed individuals from Plaza 3A are genetically distinctive to the local individuals from Huaca de la Luna; therefore, sacrificed individuals were probably brought from outside, yet nearby, populations. For Sutter and Cortez (2005), this supports the hypothesis that Moche warfare was not endemic but organized and systematic. This also resonates with Verano's ideas of Moche warriors as a class of selected individuals professionally trained and engaged in one-on-one combat using maces and other close-contact weapons (Verano 2001, 2008). More sacrificial contexts from other Moche sites need to be analyzed in order to have a better understanding of the nature of this practice and its implications in the political world of the Moche.

Rituals

The case of the sacrificed victims at Huaca de la Luna has, given shape to our understanding about the nature of Moche ritual behavior as a whole. The notion of rituals as expressions of materialized and legitimized ideological power has been and is still dominant in the study of Moche rituals (Castillo and Uceda 2008; DeMarrais et al. 1996; Donnan 2010; Uceda 2000, 2008). Moche scholars have long interpreted Moche rituals as an expression of elite power within a highly stratified social system. As Castillo and Uceda (2008) argue, political roles in Moche society were

defined and acted out in dramatic ceremonies in which elaborate ritual attire and vivid symbolic images expressed narrative concepts of Moche elite power and authority. Likewise, fine-line drawings depicted scenes of ritual actions that highlighted the primacy of political leaders during these activities. Additionally, burials of high elites mirrored their privileged roles in life. Under this perspective, the Moche perfectly illustrated the strategic role of an ideology of elite culture and its effectiveness as a source of power.

The notion that equates ritual to dominant power has nonetheless been challenged by other scholars who warn about the limitations of power-based interpretations. This claim fits well with the renewed interest of Swenson in studying the political role of Moche ritual performances (Swenson 2008, 2011). Based on the excavation and analysis of various Late Moche cult centers in the Jequetepeque Valley, Swenson argues that Moche rituals occurring in medium- and large-scale ceremonial centers could have deployed polyvalent meanings on participants that enabled them to reinforce, negotiate, or even contest political and social identities within an ever-fragmented Moche world (Swenson 2011). They were not necessarily one-dimensional mechanism aimed to impose power but bi-directional processes of negotiation and contestation.

Royal and Elite Burials: Death, and Ancestors

In 1987, the discovery of Sipán's royal tombs, the richest tombs ever found in the pre-Columbian Americas, constituted an important breakthrough not only in Moche archaeology but also in Andean archaeology as a whole (Alva 1988; Alva and Donnan 1993). The complexity and lavish wealth of the ornaments made of gold, silver, copper, and semiprecious stones contained in the tombs of the Lord and the Old Lord of Sipán put into manifesto the scale of social complexity, hierarchy, and incredible capacity of accumulation of wealth in the Moche society (see Fig. 7). At least 13 royal tombs have been found within Sipán's funerary platform in the Lambayeque Valley, showing a structured genealogy of dynastic kings that ruled the valley from the 2nd to 6th centuries AD.

After since Sipán's discovery many other royal and elite burials have been excavated both scientifically and nonscientifically (by looters and grave robbers). The northern region of the Moche territory has been especially active in producing wealthy tombs. The sites of Loma Negra (Piura Valley), Úcupe (Zaña Valley), San José de Moro, La Mina, and Dos Cabezas (Jequetepeque Valley) have yielded rich and complex funerary chambers containing one or multiple elite individuals buried along with exquisitely manufactured metal, cermamic, and stone objects as well as with sacrificed individuals.

Moche funerary chambers are adobe structures of quadrangular or rectangular shape frequently roofed with frames made of cane and *algarrobo* beams. In most cases the internal walls are decorated with niches where the most valuable offerings were usually placed. In a few cases, mural paintings have also been recorded decorating the internal walls of the funerary chambers. The Moche chambers are internally organized through platforms and internal subdivisions. The mortuary coffins were often placed either in the center of the structure or on top of a raised platform. Mortuary coffins were made of cane or wooden plaques tied with metal bonds. In San José de Moro, the coffins are also decorated with metal plaques crimped onto them (Fig. 9).

Some have suggested that the individuals buried in the royal burials of Sipán, Ucupe, and Dos Cabezas might have been related either through political affiliation or kinship (Chapdelaine 2011). For example, the Lord of Úcupe discovered by Steve Bourget in 2008 (Bourget 2008) was an adult male individual that likely ruled the Zaña Valley during the Early Moche period. He was buried personifying one of the characters depicted in the well-known scene of the Sacrifice Ceremony (see Fig. 6), where another character, which the Lord of Sipan personifies, is also being represented (Alva and Donnan 1993; Bourget 2008). The similarities between the ceramic offerings in both tombs could suggest that these Early Moche polities, Sipán and Úcupe, either could have shared political ties of cooperation or were part of a shared network of exchange. Likewise, royal burials at Dos Cabezas,

Moche, Geography and Culture of, Fig. 9 Funerary coffin made of wood and cooper containing the remains of a Moche priest from San Jose de Moro. (Photo from the archive of the San José de Moro Archaeological Program)

excavated by Christopher Donnan in 2001 (Donnan 2007), contained a group of leaders from the same dynasty that ruled the Jequetepeque Valley during the Middle Moche period. These individuals likely established ties of interchange and political cooperation with elites from Sipán and Úcupe.

Elite burials discovered in San José de Moro, by Donnan and Castillo in 1991 and 1992, provided pivotal information not only to reconstruct the pyramid of social hierarchy during Late Moche times but also to decipher how power and gender were intimately articulated in this society (Donnan and Castillo 1992; Castillo and Rengifo 2008). Seven elite burials of Moche Priestesses have been found at the site across more than 20 years of investigation. These women could have formed part of a dynasty of powerful rulers that accumulated not only wealth but also political power and primacy to lead large-scale rituals (Fig. 10).

Other royal tombs have also been found in the southern part of the Moche territory, among the most remarkable, the "Lady of Cao" in Huaca Cao Viejo (Mujica 2007). The body of this Moche princess was found wrapped in textiles and inside a frame made of golden plaques. In addition, the princess' body was incredibly well preserved, showing evidence of corporal tattoos covering her completely. Other instances of burials of upper elite individuals were excavated in Huaca de la Cruz: "the tomb of the warrior-priest" and El Castillo del Santa.

Moche, Geography and Culture of, Fig. 10 Tomb of "The Moche Priestess" of San José de Moro. (Taken from Donnan and Castillo 1992)

Although death in the Moche world appears to be a largely investigated topic, it remains, paradoxically, poorly understood. Fascination with the material wealth contained in Moche burials has caused Moche scholars to place an over-exaggerated attention on the study of hierarchy, status, and power, all of which constitute intrinsic aspects of the material dimension of death. Furthermore, the recognition and identification of the individuals found within royal and elite burials with iconographic characters identified in Moche art might result in a problematic task. The little reflexive identification of characters can lead to the dangerous assumption that roles of iconographic personages must have been the same as the real elite individuals (Kaulicke 2000). This trend, conversely, results in the fact that little to no attention has been put on the study of the "immateriality" of death and, above all, the social actions hardly visible in the archaeological record and that could be intimately linked to a particular understanding of death and the body.

In an attempt to go beyond the material wealth of the Moche burials as well as explore alternative conceptualizations of the body, Kaulicke (2000) deconstructs the notion of death by introducing the notion of transformation. He attempts to decipher the symbolic transformations of dead bodies by paying close attention to the contexts, its associations, and the symbolic contents expressed within them. "Ancestrality" and ancestor worship seem to have been ubiquitous notions in Moche society. The great amount of scenes represented in both sculptural and pictorial elite vessels suggests that Moche art could have been solely articulated around mortuary rites before, during, and after the physical decease of elite individuals (Kaulicke 2000: 34). The inhumation, and particularly the transformation of the dead into ancestors, seems to have been a process that, Kaulicke says, involved the participation of a significant number of mythical beings (Kaulicke 2000: 34).

This perspective that has become mainstream in the study of the body and death in archeology resonates with my own investigation in the Jequetepeque Valley. Excavations conducted at Huaca La Capilla-San José de Moro from 2013 to 2016 have provided invaluable data to reconstruct the Moche spectacles of death celebrated at the site during Late Moche times. The remarkable resemblance between the architectural enclosures of Huaca La Capilla, many of them finely ornamented, and the architectural models or *maquetas* recovered within the complex elite burials of San Jose de Moro suggests strong symbolic connections between Moche monumental architecture, rites of ancestrality (and transfiguration), and the concept of life regeneration (Muro et al. 2016). This later manifested in the multiple scenes in Moche art where dead individuals (likely ancestors) perform rites of copulation with living women (Bourget 2006). San José de Moro has also yielded incredibly rich data of mortuary feasting and commemorative practice associated with ancestor veneration. The more complex the burial, the greater is the evidence associated with post-inhumation rites (Fig. 11).

The concept of death is also intimately related with the cyclical renovation of monumental architecture (Kaulicke 2000: 37). Huacas throughout the Moche territory are commonly receptacles of funerary contexts either these in the form of formal burials, sacrificed individuals, or even part of human bodies. This fact is accompanied with the generalized practice of altering dead bodies through either the removal of important body parts or addition of new ones from other individuals. This pattern, as Kaulicke has suggested, would entail that the physical death of the individuals would have extended over long spans of time, which, in turn, would have been linked to funerary rites. This practice would reflect a sort of "materialized memory" upon which the Moche social and political identity was grounded (Kaulicke 2000: 40).

Huacas and Urbanism

Long-term archaeological excavations conducted in large Moche *huacas* are providing new perspectives about how the urban phenomenon in the Andes was intimately linked to the development of theocratic states in the north coast of Peru.

In the Moche world, *huacas* were an essential component of the urban phenomenon. *Huacas* not only defined the sacred and religious landscape but also the spatial organization on a domestic and administrative scale. Extensive excavations,

Moche, Geography and Culture of,
Fig. 11 Evidence of funerary feasting associated with large Moche chamber tombs in San José de Moro. (Photo from the archive of the San José de Moro Archaeological Program)

conducted by Claude Chapdelaine in the large plain located between Huaca de la Luna and Huaca del Sol at the site of Huacas de Moche (NUM: "Núcleo Urbana Moche"), have revealed a complex architectural setting composed of multiple residential units articulated by corridors, avenues, and public plazas: a true Moche city (Canziani 2003; Chapdelaine 2003). Furthermore, residential quarters would have been linked both functionally and spatially with craft workshops and storage facilities.

The Moche city would have started its growth around AD 300, namely, in the Moche III phase, if not earlier (Chapdelaine registered evidence of Gallinazo and Moche II ceramics in association with the earliest occupational floors) (Chapdelaine 2003: 272). This would demonstrate that the social and political relevance of the Huacas de Moche site in the Moche Valley could have started as early as AD 200. Although the dynamics of growth of the city is still unknown, Chapdelaine suggests that the functions of this early city would have been circumscribed to religion, administration, and craft production. Also, craft specialization would have had an exceptional development in the residential quarter of the "NUM" where a significant number of dwellers were dedicated to the full-time craft of prestigious religious objects. This seems to indicate that a true urban class emerged at the Huacas de Moche site. This urban class actively participated in the accumulation of goods giving support to the wealth accumulation and the expansion of the political agenda of the governing elites.

Chapdelaine points out that the inhabitants of Huacas de Moche were innovators in building the first capital of a unique state that grew to satisfy the needs of powerful elites whose political control disseminated across the valleys of northern Peru (Chapdelaine 2003: 199). Although the idea that these elites used military coercion to expand their spheres of interaction is still debatable, the centrality, hierarchy, and scale of the Huacas de Moche site are comparable to any other Moche site. Its prominence in the Moche Valley and beyond makes it a real first-order settlement, a true state capital.

It is likely that the growth of settlements around large Moche *huacas* was strongly related with the cycles of renovations of sacred architecture. Many authors have suggested and demonstrated that Moche *huacas* were objects of frequent burials and reburials. *Huacas* were constantly covered so that new buildings were constructed on top of the previous ones (Mujica 2007; Uceda 2000, 2010). It is suggestive thinking that this behavior could

have been conditioned to religious calendars, astronomical cycles, or the need of a new leader to legitimize his power.

Excavations in other major Moche ceremonial centers, such as Huaca Cao, have advanced our understanding of Moche urbanism. Regulo Franco and his team demonstrated that both Huaca Cao and Huaca de La Luna were constructed by following the same architectural pattern. Orientation, size, and space distribution of both buildings might have responded to a very organized plan of expansion led by ruling elites. It has been relatively accepted, though, that these Moche polities did not fight one another but rather might have operated rather through strategic political alliances.

The idea that the Moche developed the first planned cities of the New World, has both advocates and critics. The presence of state bureaucracies operating in major Moche centers is still uncertain. No administrative facilities have been found yet that demonstrate the existence of specialized officers in charge of different governmental affairs as, in fact, have been demonstrated for other ancient cities. Also the existence of palaces or royal houses is still largely unknown, a requisite that has been met by other ancient groups to attain the classification of "urban."

The lack of material evidence cannot be taken as an argument to deny Moche urbanism. Uceda (2008, 2010) holds that Huaca del Sol might have been the receptacle not only of a royal palace but also of structures where the administration of state affairs was carried out. Although excavations at Huaca del Sol have already been initiated, the results are not conclusive. The degree of destruction by looting at Huaca del Sol is overwhelming, so our understanding of how this structure looked in the past will always be incomplete.

Apparently, the organization of Moche cities was defined based on the work of specialists under the control of ruling elites (Chapdelaine 2003). These specialists satisfied the needs of the dominant groups whose power was grounded in the control of prestigious religious items and ritual knowledge. Moche cities were the expression of an incipient urbanism developed by theocratic states and theater states. These latter owed their existence to their capacity to host and organize large-scale ritual spectacles that took place in massive ceremonial structures such as Huaca de la Luna, Huaca Cao, and Pañamarca (see Fig. 3). If, on one hand, these buildings were the expression of a highly structured and hierarchical society, on the other, they constituted spaces where cultural and religious identities were reaffirmed and the social order was established by the elites. The legitimization and renewal of power was, thus, achieved through propitiatory acts, human sacrifices, feasting, and other actions of a sacred nature.

Our understanding of both the Moche and Andean urbanism as a whole is still very poor. Moche scholars need to reorient their attention from the study of large and ornamented *huacas* to the study of their surrounding areas, where middle- and lower-class populations appear to have massively settled. Excavations in sites such as Pampa Grande (Shimada 1994) and Galindo (Bawden 1982, 1995) have provided important data on the social tensions that emerged in two highly hierarchical Moche V large-scale settlements. Excavations in the areas surrounding Sipán need to be conducted with urgency, not only because of the serious threats of destruction by modern inhabitants but also because it is imperative that we understand the social dynamics and urban development in this Moche site that has produced the most significant evidence of hierarchy and royal lineages.

Collapse

The fall of the Moche is a topic that has awakened hot debates among Moche scholars. Twenty years ago, the relatively accepted consensus was that the demise of the Moche occurred at some point between AD 500 and 600 (Moseley 1992; Shimada 1994; Shimada et al. 1991). According to this theory, the occurrence of a devastating El Niño phenomenon would have led to the political and economic weakening of the ruling elites and, subsequently, to their imminent demise. This theory was largely supported by the data obtained from the Quelccaya Ice Cap, which determined periods of major precipitations followed by drastic droughts hitting the north coast of Peru from

AD 563 to 594. The data from Quelccaya were additionally utilized as a basis for explaining the major social and political transformations occurring on the Peruvian coast as a whole between the sixth and seventh centuries AD (Shimada et al. 1991). As a result, sites such as Huacas de Moche would have been devastated and rapidly abandoned by its population. This idea was also supported by Moseley who registered at this site thick layers of mud and sediments on the flat areas surrounding the ceremonial mounds (Moseley 1992).

New research has demonstrated, however, that the environmental instability produced by the major rainfall and droughts did not necessarily trigger the demise of the Moche state apparatus, but rather radical transformations in settlement organization, subsistence patterns, and defensive strategies. Chapdelaine (2003) demonstrates, in light of new finds in the Huacas de Moche urban complex, demonstrates that the abandonment of the Moche city would have occurred only after AD 700 suggesting, thus, that the Moche IV phase would have lasted longer than originally believed. Uceda seconded this hypothesis based on evidence retrieved at Huaca de La Luna's New Temple. He argued that the site was completely abandoned by the Moche only after AD 850 (Uceda 2010).

Now it is known that the transformations occurred as a result of environmental stress that produced the emergence of new Moche sites such as Galindo and Pampa Grande in the valley necks of the Moche and Lambayeque Valleys, respectively. The relocation of highly nucleated and populated settlements from the lowlands to valley necks must have been motivated by the search for new and safe arable lands and water, whose control led to scenarios of political struggles and conflict.

While some scholars have prioritized environmental and external factors to explain the fall of the Moche, others have paid much more attention to the internal causes that triggered the rupture of the political and ideological structures in the Moche world. Shimada, for instance, found evidence of selective burning on most of Huaca Fortaleza – Pampa Grande, with little sign of disturbances elsewhere at the site. He postulated that the conflictive relationships between an opressive elite (Moche) and oppressed populations (Gallinazo) triggered a revolt that led to the intentional destruction of the huaca (Shimada 1994: 56). In addition, he came to the conclusion that the Moche state capital, in the Moche Valley, had potentially been relocated to the Lambayeque Valley around the seventh century AD and as the consequence of the environmental crisis (Shimada 1994: 63). Pampa Grande would be the expression of the phenomenon of relocation. This assertion is, however, still debatable due to the uncertainty of the scope of geographic applicability of the Quelccaya ice core analyses.

Shimada's internal-conflict-based interpretations resonate with the influential work of Bawden at Galindo (Bawden 1982, 1995). Bawden examines the relationship between the underlying north coast social structure and the short-term processes and events that gave shape to the Moche cultural identity in a specific time and space. The ever-conflicted relationships between structure and historically constituted agency continuously threaten social systems: a structural paradox (Bawden 1995: 271). Historically constituted agency was inevitably produced by the inherent contradictions of Moche political ideology, which always opposed the intrinsic Andean tenets of reciprocity and solidarity.

The role of ideological negotiation was, therefore, essential in the Moche world, above all, in scenarios of political and social crises. It is suggestive to think that Moche elite groups adapted and readapted the mechanism of ideological manipulations to further legitimize their authority and social privileges. Swenson, in investigating the site of San Ildefonso in the Jequetepeque hinterland, argues in favor of a process of "popularization" of Moche religion as well as of propagation of multiple ideologies in the Late Moche period (Swenson 2008). This phenomenon is evidenced by the remarkable redundancy of ramped platforms at the site whose construction and management must have been sponsored by relatively autonomous social groups that periodically congregated at the site. This phenomenon would have been a reaction against Moche urban

elites of the neighboring valleys and represented an attempt of self-empowerment as well as the appropriation of the symbolic capital of urban elites.

Unlike Swenson, Castillo bestows greater agency to the Moche elites who intentionally redesigned the strategies of ideological negotiation and manipulation. Based on funerary evidence from the Late Moche site of San José de Moro, in the Jequetepeque Valley, Castillo holds that the presence of the southern state of Wari in the Moche territory had an indirect, yet triggering, role in the collapse of the Moche elite at the site (Castillo 2000b, 2001). Fine ceramic objects of Wari and Wari-related styles have been found within the most prestigious Moche burials of San José de Moro. In addition, hybrid Moche-Wari objects also accompany the funerary assemblages. These objects, however, neither prevail in number nor are the most important objects within the funerary contexts. Wari symbols seem to have been reinterpreted and re-elaborated for intermediate societies associated with Wari as well as with Moche elite of San Jose de Moro.

Castillo's thesis differs from other interpretations that consider that the north coast was under military and political control of the Wari Empire. As Castillo argues, there is no real evidence of coercion or political confrontation in any of the Moche sites showing Wari presence (Castillo 2000b, 2001). Far from being unilineal and homogeneous the Moche-Wari relationship appears to have been of a multidimensional nature and historically contingent (Castillo et al. 2012). Castillo thus highlights the ideological contradictions that emerged once Moche ideology came into contact with foreign political and religious ideologies. While the introduction of foreign prestigious objects to the Moche sphere of interaction was considered a strategy of ideological and political reinforcement by the elites, the influence that these objects exerted could, at at the same, have accelerated the deterioration of the ideology associated with Moche elite .

Similar to the hypotheses about the origin of the Moche, there is an accepted consensus that the collapse of the Moche was also manifold (Castillo and Uceda 2008). The evidence suggests that there were multiple collapses, which occurred under various circumstances, and for a number of reasons and momenta. The Moche(s) were composed of multiple political entities, all of which emerged, developed, and collapsed under particular cultural and historical contexts. These contexts triggered complex processes of development lasting tens if not hundreds of years. Once the Moche fully disappeared from the archaeological record, power relations and authority reconfigured in the north coast of Peru resulting in the origin of later state entities such as Lambayeque and Chimu whose elites ruled the region until the Spanish conquest.

Modern Material Culture, Archaeology of

Claire Smith, Jessica Lowther and Jordan Ralph
College of Humanities, Arts and Social Sciences, Flinders University, Adelaide, SA, Australia

Introduction

The archaeology of modern material culture, also known as archaeology of the contemporary past, has received increasing attention over the last 40 years. There have been two distinct stages in the development of this area of research. The first occurred during the 1970s and 1980s, when archaeologists in the United States began to question two core views of archaeology: that archaeological sites are only those that are concerned with a distant past and that archaeological information is obtained through excavation (Rathje 1981: 51–52). The questioning of these two assumptions led to the emergence of modern material culture studies as a sub-discipline within archaeology.

As Leone (1981: 7) points out, modern material culture studies developed two principal lines of inquiry. The first was investigation of the relationships between modern societies and their material culture to better understand material patterning in past societies is often described as ethnoarchaeology. The second line of inquiry was the analysis of what modern objects can reveal about present-day societies (e.g., Rathje 1974), with the aim of yielding information about an aspect of culture that is not always seen by those creating or using the materials (Leone in Gould and Schiffer 1981: 7). In the early 1990s, this area of study received a significant boost with the publication of Tilley's (1990) volume *Reading Material Culture*.

The second major phase in the development of archaeology of modern material culture emerged in the 2000s. During this time there was a greater recognition of the active role that material culture plays in the negotiation of social relationships. As Hodder (2012: 33) explains it, "materials and things are seen as actively engaged in the social process" and self and society cannot be "studied independently of materials and the object world." One expression of this trend is a tendency to replace the phrase "modern material culture" with the term "material practices" (e.g., Thrift 2008) or archaeology of the contemporary past (e.g., Graves-Brown et al. 2013). Furthermore, Hudson (1984) iterates that modern material culture "looks at the interaction between material culture and the behavior it reflects" (Hudson 1984: 32). During the 2000s research into modern material practices became increasingly directed into areas such as the analysis of what Meskell (2005) calls the archaeology of materiality, investigating homelessness, conflict and protest, multiculturalism, and social justice and following the approach of an engaged archaeology (Smith and Ralph 2019). An ethnoarchaeological emphasis on material culture analysis to develop theories to understand material patterning in past societies has remained a strong facet of this area (e.g., Politis and Alberti 2007). However, the argument that archaeology should be concerned with

understanding the distant past has largely disappeared from view, as the proponents of material culture studies work from the position that archaeology is about material practices, not time, and that therefore "the past" can be anything as small as a nanosecond gone by.

Definition

The archaeology of modern material culture is the study of society through its contemporary material remains, both real and virtual, as situated within cultural landscapes, both real and virtual. This definition draws on Smith's (2017: 7) definition of archaeology as "the study of human behaviour, past and present, through the analysis of material culture, both real and virtual, as situated within cultural landscapes," rather than the more traditional, and more bounded, definitions of archaeology as the material traces of past societies.

The archaeology of modern material culture can be defined as the archaeological study of material artifacts and landscapes that are related to the modern and postmodern period, often characterized as from the end of the Second World War to the present (cf. Harrison and Schofield 2010). Building on Rathje's (1981) earlier arguments, an important step in the redefinition of archaeology as a discipline was Harrison's (2011) call to replace the modernist trope of archaeology-as-excavation and the idea of a buried past with the alternative trope of archaeology-as-surface-survey and as a process of assembling/reassembling. González-Ruibal (2008, 2019: 12) argues that the period of interest to contemporary archaeologists is "supermodernity," which he explains is "modernity gone excessive – and awry." This distinction is based on the potentially unsuitable definitions of modernism and postmodernism, which, he contends, are periods that are temporally too short to be of real use to archaeologists, who tend to define archaeological periods in much greater length. Instead, González-Ruibal (2008) argues that we should look to the technological and material origins of the contemporary world and that the period of the First World War (1914–1918), the "horizon of destruction," might be more appropriate, though it could be earlier (González-Ruibal 2019: 13). Harrison and Schofield (2010: 2), in an earlier attempt at theorizing contemporary archaeology took a different approach, using the second half of the twentieth century as a marker for the period of interest to contemporary archaeologists, as "[t]his period encompasses the end of the Cold War and the beginning of the 'internet age', a period that sits firmly within what we would recognize to be one of 'lived and living memory."

While neither of these approaches seek to prescribe what should and should not be the object of contemporary archaeologists, they instead seek to provide more clarity to the often blurred boundaries of the subfield. Though contemporary archaeology has gained much academic traction, it largely remains undertheorized, despite the welcome and critical attempts by Harrison and Schofield (2010) and González-Ruibal (2019). Regardless of the timing of contemporary archaeology, the fact remains that the interest of contemporary archaeologists is the material culture and landscapes that are produced by contemporary societies. Their study can provide insights into an increasingly globalized world, particularly in terms of consumption, excess, disposability, and social inequality but also in terms of new modes of industry, conflict, and migration (see Mizoguchi and Smith 2019). Places and things of interest to contemporary archaeology can take many forms; in a contemporary urban setting, it might be the contents of someone's home, their vehicle, and other objects with which they interact. It could be the way a person or group has altered the physical landscape (see Hamilakis 2016; Mizoguchi and Smith 2019); or it could indeed be the way in which items from the distant past are reused in the present. The potential applications of contemporary archaeology are vast, and below we provide an overview of some recent examples. Finally, the strength of this field of study has been recognized in the current definition of archaeology used by the Society for American Archaeology, which now defines archaeology as "the study of the ancient and recent human past through material remains" (SAA 2019).

Historical Background

The archaeology of the contemporary past has undergone several key theoretical developments since its inception in the 1970s and 1980s. More recently, there have been attempts to theorize the subfield of archaeology, to determine the boundaries, or lack thereof, of contemporary archaeology (see González-Ruibal 2019; Harrison and Schofield 2010). The foundational volumes of contemporary archaeology (see individual contributions in Gould and Schiffer 1981; Rathje 1974, 1981) often applied existing methodological approaches to modern material culture and modern landscapes in what was then an innovative development for the discipline. The term "modern material culture studies" was first used to describe archaeologies of the contemporary past, though in the early twenty-first century, "archaeologies of the contemporary past" became a preferred term, not least because of the publication of Buchli and Lucas' (2001) *Archaeologies of the Contemporary Past*.

In essence, the two terms refer to the same practice. However, a key distinction is that "modern material culture studies" developed from varying approaches to ethnoarchaeology in the USA, while "archaeologies of the contemporary past" was developed by researchers in the UK and parts of Europe who were more interested in the "archaeology of us," where contemporary archaeologies could be used as a "critical intervention in contemporary society" (Shanks and Tilley 1987). Instead of the initial approaches to studying the contemporary, which were focused on the ethnoarchaeological and pedagogic value of such studies, archaeologies of the contemporary past became focused on the value of archaeology in understanding the present, as Buchli and Lucas (2001: 8) argued regarding the knowledge and themes presented in the various studies included in their volume, which "only archaeological approaches could have uncovered these themes."

Studying modern material culture reveals much about our own society. Hudson (1984: 34) argues that "the sum total of a society's artifacts. . . function as a mirror of its patterned values, beliefs and social structure." From this viewpoint, the analysis of modern material culture can address bias and contribute to a more holistic representation of a society's social, cultural, and cognitive patterns.

Key Issues/Current Debates

One of the key issues surrounding the archaeology of the contemporary past is the potential for debate around archaeological significance. Rathje's (1974) Garbage Project at the University of Arizona, which began archaeologically recording household waste as it was discarded (Shanks et al. 2004: 65), is perhaps one of the most well-known modern material culture studies and one that received considerable has criticism. At the time, few archaeologists conceded that the project was archaeology at all on the grounds that the garbage was not old enough to warrant archaeological analysis (Shanks et al. 2004: 66).

Rathje defines four key ways in which modern material culture studies contribute to archaeology. Firstly, he contends that teaching archaeological principles can be easily achieved through studying modern material culture; as after studying ourselves comparably to the ways we study past societies, students will be more equipped to approach traditional archaeological data (Rathje 1981: 53–54). Secondly, Rathje argues that core archaeological principles, including methods such as ethnoarchaeology and experimental archaeology, can be tested in modern settings (Rathje 1981: 53). Thirdly, he contends that modern material culture studies contribute to the recording of cultural history and to understanding processes and relationships between people and material culture that might otherwise be lost. Lastly, Rathje proposes that modern material culture studies can be used to identify continuing trends between past societies and those of the modern day (Rathje 1981: 55). This is particularly interesting when applied to a contact situation in which materials from more than one culture are combined in new ways (e.g., Fig. 1).

Material culture studies are a flourishing and rapidly expanding subfield in archaeology. Present emphases include the analysis of modern patterns of consumption, urban heritages, social housing, homelessness, conflict and protest,

Modern Material Culture, Archaeology of, Fig. 1 Modern material culture in a contact environment. Bough shelter for the deceased. Aboriginal community of Barunga, Northern Territory, Australia, 2015

multiculturalism, migration and displacement, digital environments, and contact studies. We recommend the work of Zimmerman et al. (2010) and Leone (2010) in the USA; Schofield and Kiddey (2011), Harrison and Schofield (2010), and Hicks and Beaudry (2010) in the UK; Meskell 2012 and Shepherd (2003) in South Africa; Frederick and Clarke (2016) and Ralph and Pollard (Pollard et al. 2017) in Australia, Holtorf (2012) in Sweden, and González-Ruibal (2008, 2019) in Spain.

There is an increased emphasis on inequality, exclusion, racism, and social justice, especially through the analysis of signs and images which focus on a particular social group, but at the same time excludes others who are from a different demographic (e.g., Fig. 2). Many projects have some urgency, as the material objects are ephemeral. In their study of the archaeology of homelessness, Schofield and Kiddey aimed to engage the homeless community of Bristol (UK) in an active heritage project mapping the archaeology of the homeless participants, essentially "constructing an archaeology of themselves" (Kiddey and Schofield 2011: 5), which focused on connections between heritage practice and policy and the benefits of participation by excluded or minority groups. This study actively involved many local homeless people who oriented the archaeologists on the material culture left behind by homeless people, including why it was there and what it meant, as some of the material culture, such as drug paraphernalia, was unfamiliar to the archaeologists. This study highlights one important reason for conducting modern material culture studies when information is still available about artifacts within the communities using them: had the archaeologists not been assisted by local people artifacts could have gone unrecorded, different meanings could have been deduced from the material culture, and an element of the patterns of the society of the homeless population of Bristol would have been lost. Furthermore, studies such as that of Zimmerman et al. (2010) and Pollard (see the entry on "▶ Homelessness, Archaeology of" in this encyclopedia) push boundaries of this subfield through a deliberate focus on informing government policy.

Three examples of archaeologies of modern material culture/the contemporary past are archaeogaming, the archaeology of displacement and forced migration, and space archaeology.

Modern Material Culture, Archaeology of, Fig. 2 Images of exclusion, Adelaide Airport, South Australia, 2013

Archaeogaming

Serious games have been an emergent archaeological interest since the 1990s and early 2000s, most notably through tools for public outreach, such as *Adventures in Fugawiland* (Price and Gebauer 1990), and, later, through excavation of the Atari Burial Ground in Almogordo, New Mexico (Reinhard 2015). However, only recently has this interest emerged as a sub-discipline of archaeology. The trend is captured in the term "archaeogaming," which was coined by Andrew Reinhard, as the name of an internet blog dedicated to discussion of the archaeology both of and in video games (Reinhard 2013). This includes consoles, computers, and mobile devices. Reinhard's (2018) book, *Archaeogaming*, is the first comprehensive study of archaeology and video games. It focusses on video games as artifacts as well as how material objects, spaces, and resources are used to construct game spaces.

This area is still developing, still finding its shape. Important studies in this process include *Okapi Island* and *Rosewood: An Interactive History*. *Okapi Island* was designed by Ruth Tringham as an interactive learning resource for archaeology students at the University of California, Berkeley. It is based on the 9000-year-old mound village of Çatalhöyük, Turkey. Similarly, Edward Gonzáles-Tennant's (2018a) *Rosewood: An Interactive History* grew out of his archaeological work on the 1923 race riots and massacres of African Americans in the Florida town of Rosewood (González-Tennant 2018b). This program allows users to interact with the material culture of the time period, access archaeological and documentary data, and hear audio recordings of survivors and descendants. While these platforms have been discontinued due to high operating costs, they demonstrate the potential of an internet environment to transmit archaeological knowledge about the past. This is a growing

trend, especially in economically advantaged countries. Future developments are likely to produce innovative ways of engaging with the past in the present. However, this could increase the gap of knowledge, skills, and interests between countries that have well-developed internet infrastructure and those that do not. As it stands, archaeogaming is largely the study of the gaming environments of wealthy countries. Of course, the internet can be used to bridge such gaps, and the work of Gonzáles-Tennant serves as a model for this.

The groundbreaking development is the application of archaeological theories and methods to virtual environments. As Aycock and Bittner (2019) point out in their analysis of the 1980 Apple II game *Mystery House*:

> Computers clearly introduce a level of abstraction that challenges the approaches of traditional fields like archaeology, and the rise of archaeogaming as a subdiscipline reflects the need to address these provocations to method and theory.

Economic Migration, Forced Migration, and Displacement

Another current trend is the archaeology of economic migration, forced migration, and displacement. There are a number of studies that have played a role in recording and ameliorating some of the distress and cultural trauma involved in this process. Here, we look at one example that focusses on the journey and one that focusses on refugee camps.

New insights into the experience of illegal migrants and into US government's federal border enforcement policy are offered in De León's (2015) study of those who cross the Sonoran Desert border between Mexico and the USA. This multifaceted interrogation of the social impact of the federal border enforcement policy highlights the manner in which this policy encourages illegal migrants to cross in extremely harsh environments with a high risk of death. De León argues that border-crossing artifacts both reflect and shape a way of being that is specific to the desert migration process. This ranges from desert memorials and artifacts relating to nonlethal injuries, such as blisters and dehydration, to the placement of guards around common entry points "as a deterrent to would-be crossers and a signal to people that they should try their luck in more remote parts of the desert" (De Leon 2015: 318). He contends that the deaths of people who are directed toward the more dangerous routes is neither random nor senseless but part of a strategic federal plan that aims to deter migration through the high numbers of deaths.

The conflicts in Syria and Iraq have forced people to migrate to other parts of the world. Often, this involves a period of residency in a refugee camp. The standout archaeological project here is Brian Tomaszewski work at the Za'atari refugee camp, Jordan. This involved residents conducting field surveys to establish detailed maps of the camps (Tomaszewski 2017). These maps addressed issues that were fundamental to the efficient running of the camps, such as the location of schools, mosques, and health centers. The participants obtained new skills that included the production of professional quality maps, which ensured sustainability when the research team was gone. In a situation where people are severely constrained using their normal abilities, the participants were able to acquire new skills and contribute to addressing the management and spatial challenges that arose from the every-changing layout of the camp.

Space Archaeology

Space archaeology is the study of "the material culture relevant to space exploration that is found on earth and in outer space . . . and that is clearly the result of human behavior" (Gorman and O'Leary 2013: 409). One key aim of space archaeology is to investigate material culture assemblages in order to understand the interaction of technology and human behavior in off-Earth environments. Research in space archaeology has investigated terrestrial infrastructure such as launch sites, tracking stations, and industrial complexes, satellites and orbital debris, lunar landing sites, Martian landing sites, and museum collections, managing the heritage values of terrestrial and lunar space sites.

Space archaeology includes the management of "space junk," which is nonfunctioning orbital debris made by humans. In 2020, more than 29,000 pieces

of space debris larger than 10 cm are being tracked in Earth's orbit. This debris includes abandoned satellites and rocket stages and small objects that were lost in space. This material is not just junk. It also has a social dimension, and it can provide insights into matters such the competition between the USA and the USSSR during Cold War. Moreover, these objects are part of the cultural heritage of humankind, and some need to be preserved as part of the story of human evolution. Space archaeologist, Alice Gorman (also known as Dr. Space Junk) compares Tranquility Base on the Moon, with its iconic astronaut boot prints, to the Palaeolithic footprints of *Australopithecus afarensis* at Laetoli in Tanzania. Space archaeologists argue that the entire solar system is a cultural landscape. From this viewpoint, Gorman (2019) points out that both Tranquility Base and Laetoli represent evidence of major evolutionary turning points.

Increasingly, the study of modern material culture is being used to shed new light on government policies by identifying cultural values that are internalized as part of a person's or community's worldview or by interpreting material patterning in terms of the success or failure of government initiatives (e.g., Zimmerman et al. 2010, Ralph and Smith 2014, De Leon 2015 and Pollard et al. 2017). Material analyses can provide new knowledge. The presence or absence of particular forms of material culture can be used to identify cultural attitudes to particular routines, processes, and disciplines. The absence of clocks and watches, for instance, might imply an inability to tell the time and/or an absence of time routines and work disciplines, as in Leone's (1999) and Handsman's (Leone and Handsman 1989) studies of eighteenth- and nineteenth-century Annapolis, and the many studies that have been inspired by this work. Moreover, material culture analyses can identify cultural inhibitors and physical barriers to engaging in activities such as education and employment that can allow people to improve their individual situations. Such research has the potential to provide the basis for the policy recommendations in skills training and cross-cultural communication. Though the archaeology of the contemporary past has been a focus of archaeological attention since the 1970s, these studies are undergoing a major rethinking in the early part of the twenty-first century. Current studies are grounded in nuanced analyses of contemporary lives, providing new insights that can only be gained through archaeological analysis.

International Perspectives

While archaeologies of the contemporary past surfaced first in the USA (Gould and Schiffer 1981; Rathje 1974, 1981), more recent work in developing this mode of archaeological enquiry has occurred in the UK (e.g., Harrison and Schofield 2010 and Graves-Brown et al. 2013) and Europe (e.g., Holtorf 2005, Burström 2009, and González-Ruibal 2019). Australia also has a strong community of scholars focused on archaeology of the contemporary past (see Frederick and Clarke 2016). While most agree on the value of contemporary archaeology to the broader discipline, there have been a number of debates around the contributions this form of archaeology can make contemporary societies. One of the key developments of contemporary archaeology was from a mostly heuristic practice, to one which sought to reveal and provide nuanced commentary on hidden aspects of contemporary societies. The question, now, is how we should go about that – in terms of both ethics and methodology. Harrison and Schofield (2010: 74) warn of the possibility for contemporary archaeologies to become voyeuristic when recording sites still in use, "to what extent might a study of street homelessness amount to voyeurism, and does the participation of a few street homeless volunteers make it an acceptable study, or is voyeurism made worse through tokenism?" Harrison and Schofield also question as to whether these interventions into living communities might cause harm, where even though community leaders have supported the project, community members may disagree, which could then lead to anger. González-Ruibal (2019) argues that the domain of archaeologists should be the archaeological, that is, material culture no longer in use. Further, he argues that blurring the lines between

archaeology, anthropology, and history could lead to a weakened archaeology. While the warnings of Harrison and Schofield coupled with Gonzáles-Ruibal's attempts to delineate contemporary archaeology are astute, they are from a European perspective and may not apply to settler/colonial nations, such as the USA, Canada, Australia, and New Zealand. Further theoretical developments from archaeologists from these regions are needed to further strengthen the sub-discipline.

Future Directions

Our attempts to theorize the archaeology of the contemporary past have incorporated the necessary developments towards archaeologies that provide a critical intervention. in the present. These approaches help us understand our world, particularly in relation to human-thing relationships, which is an area where archaeology and archaeologists are specialists. In terms of future directions for the archaeology of modern material culture, it is important to critically engage with what, why, and how of we undertake these archaeologies. While archaeologists in the USA lead the initial theoretical discourse, archaeologists in the UK and Europe have been responsible for the majority of recent academic labor around theorizing the sub-discipline. More voices are required in this discourse – particularly from those in Oceania, Africa, the Americas, the Middle East, and Asia – if we are to fully realize the potential of the archaeology of modern material culture.

There is a need for global studies that focus on the material (and immaterial) culture of everyday life, seeking to find not only the ways in which societies are linked, or the things that they have in common, but also aiming to identify the unique characteristics of particular societies. The potential for this approach is demonstrated in our study of Japan, well recognized as being a polite society. What are the material manifestations of this politeness? Some of its material dimensions are shown in Fig. 3. They include shelves to hold customer's shoes in restaurants in restaurants to keep the

Modern Material Culture, Archaeology of, Fig. 3 Archaeology of polite society. Fukuoka, Japan. 2016

floors clean, grooved lines on the pavements to guide blind people as they traverse the city, a stand to hold shopping or handbags in apartment buildings while you search for your key, and face cloths that are ubiquitous (and highly female-gendered) for cleaning sweat from your face in hot and humid weather. Modern material culture in Japan is designed to help society to be more orderly, safe, and clean and to remind people to be aware of the needs of others. In doing so it smooths the everyday lives of people in Japan.

Finally, we must not consign the development of contemporary archaeologies to theoretical debates. We need more dedicated archaeological studies that focus on contemporary materials and landscapes to further establish the potential applications and ethical boundaries of such inquiries. A major challenge will be dealing with the effects of humans on climate and the environment as part of the Anthropocene (e.g., see George and Edgeworth 2018). The insights, narratives, and data that come from the practical applications of contemporary archaeology have been invaluable to the articulation of the sub-discipline, and further dedicated studies will continue to strengthen this developing mode of archaeology.

Introduction and Definition

The word *ruin* is an ambiguous and contested one. In our everyday comprehension, it easily brings to mind ancient and enchanted monumental structures, an archaeological dream world featuring celebrities such as Machu Picchu, Pompeii, and Angkor Wat. For centuries, classical and Gothic ruins inspired poets, artists, and scholars, motivated philosophical mediations, and served as instruments of contemplative and aesthetic pleasure. At the same time, the word *ruin* also has a strong negative tone to it. According to the *Concise Oxford Dictionary*, "To ruin is to inflict or bring great and irretrievable disaster upon, to destroy agency, to reduce to a state of poverty, to demoralize completely" (1964: 1095). In this active verb form, it is almost entirely associated with negative and violent processes, with destruction and demolition (Stoler 2008: 194; Japelli 2012).

While the way we think of *ancient* ruins hardly is affected by these dismal and destructive connotations, our attitude toward the ruins of the recent past is indeed very different. Through the rise of capitalist economy in the nineteenth century, mass production, consumerism, and cycles of material replacement have accelerated; increasingly larger amounts of things are increasingly rapidly victimized and made redundant. The outcome is a ruin landscape of derelict factories, closed shopping malls, overgrown bunkers, and redundant mining towns: a ghostly world of decaying modern debris normally left out of academic concerns and conventional histories. Lingering on at the outskirts of society, these redundant sites become places of abjection, giving face to a past too recent, too grim, and repulsive to be embraced as heritage (González – Ruibal 2008). Though this attitude is being challenged, as reflected in the growing archaeology of the contemporary past (e.g., Buchli and Lucas 2001; Burström 2007; Holtorf and Piccini 2009; Harrison and Schofield 2010; Olsen and Pétursdóttir 2014) and the broader popular, artistic, and scholarly interest in decay and ruination (e.g., Woodward 2002; Elíasson and Sigurðsson 2004; Edensor 2005; Hell and Schönle 2010; O'Boyle and Manaugh 2010; Romany 2010; Rowsdower 2011; DeSilvey and Edensor 2012; Mah 2012; Gordillo 2014), modern ruins still play a very marginal role in the political economy of both the past and the present.

In this entry, we shall first explore some of the causes for this othering and for the ambivalent attitude toward the ruins of the recent past. Why is it that the ruins of our own time have been considered so devoid of value – historically, aesthetically, culturally, and scientifically – compared to their ancient comrades? And, secondly, why *should* we really care about this rubble; why do these stranded beings deserve our attention? Crucial to this discussion is the materiality of memory and the historical significance of things. Is ruination just a negative process that brings "great and irretrievable disaster upon" its victims? Or can it also be seen as a mode of disclosure that enables the recovery of memories that usually do not find their way to the historical or contemporary narratives: the neglected, unsuccessful, and ineffable? A third and final topic to be explored is how the ruins of modernity *are* and may be integrated in contemporary cultural processes and critique. How their deconstructive agency may contribute to a critical aesthetics and how their ruined physique provides spaces for alternative

cultural practices. To sum up, what is the possible capital or affordance of modern ruins?

Key Issues and Current Debates

Untimely Ruins

Given the attention and care that ancient ruins are being subjected to, it is timely to ask, what is wrong with modern ruins? At first, we should note that there is an effective history of norms, values, and distastes involved. Throughout the nineteenth and early part of the twentieth century, architects, artists, and other intellectuals felt a growing concern for the development of what they considered inauthentic architecture: the vulgar iron, concrete, and glass works of contemporary engineers, as expressed, for example, in arcades, exhibition halls, factories, and bridges. One argument used to denounce these constructions was that they lacked "ruin value;" they could not produce gentle ruins of the kind left to us from classical antiquity (Yablon 2009: 8). The famous English poet, artist, and critic, John Ruskin, for example, refused to count iron constructions ("the iron roofs and pillars of our railway stations") as architecture, partly because the constructors did not have true command over iron's "modes of decay" (Ruskin 1849/2001: 68–69). Later and more infamously, the notion of ruin value that was claimed developed to a "theory" (and even a "law") by Nazi architect Albert Speer. Unable to age and ruin in a graceful way, Speer claimed that modern materials and constructions were unsuited to form the wished for "bridge of tradition" that could inspire future generations. It was "hard to imagine that rusting heaps of rubble could communicate the heroic inspirations which Hitler admired in the monuments of the past" (Speer 1970: 97).

Connoisseurs of ruins have always favored stone, the preferred building material of the archetypical ancient civilizations (Yablon 2009: 8; Cnattingius and Cnattingius 2007: 10). Modern ruins, on the contrary, are made of iron, glass, and concrete, wrong materials that do not know how to age and decay in a proper manner (Fig. 1). Their very fabric and substance prevents them from fulfilling the aesthetical expectations associated with a "proper ruin." As voiced in a recent publication, through their ruination, they will rarely be able to evoke the scenic mood needed for the

Modern Ruins: Remembrance, Resistance, and Ruin Value, Fig. 1 Wrong materials, wrong age. The abandoned herring rendering factory at Eyri, NW Iceland. (Photo: Þóra Pétursdóttir)

structure to proceed on to the category of "ruins" (Cnattingius and Cnattingius 2007: 10).

Another serious defect of modern ruins is of course that they are *young*, and their presence thus acts as a temporal disturbance, a noise that challenges our assumptions of time, history, progress, and sustainability. In the dominant conception, ruins are *old*; they have an "age-value" (Riegl 1903/1996) that is imperative to their legal and cultural-historical appreciation as heritage (Cnattingius and Cnattingius 2007: 12). In Norway, for example, unless otherwise specified, the monument, site, or object must not be dated later than CE 1537 in order to be certified. Judged by this criterion, modern ruins become ambiguous, even anachronistic. However, this untimeliness (after Yablon 2009) is not only provoked by being ruins of a wrong time, modern ruins are also untimely due to their wrong pace. Because although age-value, according to Alois Riegl, is at first glance revealed ". . . in the monuments' outmoded appearance" (1903/1996: 72), value, he argues, does not increase in direct correspondence to age but with the ruins' slow and uninterrupted "growth into decay" (Riegl 1903/1996: 73). Orderly decay should bear no signs of rupture or destruction, and hence, the signs of "premature aging" in modern structures are mostly seen as anything but an indication of value. The ruin, moreover, should express the kind of peaceful unity and balance with its surroundings, so that ruination may appear as the natural state of structure, and not as an unnatural rupture from its authentic being. Something which modern structures, according to Georg Simmel (1911/1959: 263), are capable of only "as if in afterthought." They pollute and disturb rather than merge with or complete a historical horizon.

Unlike classical ruins presumed to have decayed slowly and gracefully over centuries, modern ruins are often *fast* ruins, sometimes *too* fast. As Alexis de Tocqueville exclaimed after encountering an abandoned settlement in frontier New York in the 1830s, "What! Ruins so soon!" The French political thinker and traveler was struck by the radical contemporaneity of the American ruins; they were, he claimed, "day-old ruins" (Yablon 2009: 10, 20). Today we see even more extreme examples of premature ruins, sometimes preceding their own completion (Fig. 2) (e.g., Pálsson 2012; Ulfstjerne 2016). While this is of course the sad reality of many war-torn areas, the current financial crisis, for example, has made such premature ruins conspicuous in many less anticipated contexts: abandoned construction sites, holiday resorts closed before the first guest arrived, apartment houses, and even entire towns that conveniently have skipped the habitation phase and turned themselves into what artist Robert Smithson has called "ruins in reverse," structures that "don't fall into ruin after they are built but rather rise into ruin before they are built" (quoted after Yablon 2009: 12).

Modern ruins, however, are also difficult to cope with for a number of other and perhaps more subtle reasons, and one particular mode of their being may prove to be especially significant. As noted above, the term "ruin" is an ambiguous one, which can grasp ". . .both the claim about the state of a thing and a process affecting it" (Stoler 2008: 195). There is, moreover, a causal tendency to see the noun (ruin) as a frozen form, inert and passive, in contrast to the active and transient verbal form (*to ruin*). Our conception of ancient ruins belongs predominantly within the first mode. The ancient ruin is clean, fossilized, and ready-ruined; it is somehow finished and terminated (see Fig. 5). The ruins of the recent past, on the other hand, have usually not reached this state but are caught up in the ongoing process of ruin*ing* – of "unfinished disposal" (Hetherington 2004). And it may well be that it is this state of being in-between, of not belonging, that also makes the ruins of the recent past so disturbing (e.g., Burström 2009; Pétursdóttir 2014).

A parallel may be made in the context of the human body. This body is attractive and pleasing – or at least tolerable – basically in two states of its being: either as a living, functional body (preferable young, healthy, and beautiful) or as de-fleshed osteological remains, as clean bones (the latter moreover subjected to their own peculiar baroque and romantic aesthetics). It is not so attractive during its transformation between these two states, when the human fabric disintegrates and flesh decomposes and rots. Modern ruins are

Modern Ruins: Remembrance, Resistance, and Ruin Value, Fig. 2 Rising into ruin. Unfinished apartment block in the small town of Teriberka, Kola Peninsula, Russia. Started shortly before the fall of the Soviet Union, the construction of this building was brought to an end following the collapse. Instead, it became a valuable brick resource for the local population. (Photo: Þóra Pétursdóttir)

often in this "fluid state of material becoming" (Edensor 2005: 16); they are ruins in the making and in a number of ways affected by this ambiguity toward the fluid and transformative. Caught up somewhere in between disposal and history and waste and heritage, they are deprived of their former functional or useful value and yet seem unable to take on, or be granted, a cultural significance.

Ruin Memories

This leads us to our second matter of discussion: What is the value of this modern debris? Can we speak of a "ruin value" that is not conditioned by the often dubious effective historical connotations of the term? And why should ruins of our own time be objects of care and concern?

One argument relates to memory and the ruins' potential of challenging dominant perceptions of history and the past. Modernity is often said to be characterized by its detachment from the past. The past, we are told, is over and gone and remains only as a subject of historical inquiry: something to be recalled and reconstructed in our historical narratives. As the narratives proceed, the past is constantly left behind; former periods are replaced by later periods. Things, however, the material residues of all these replacements, object to this pace of history. Though aging and transforming, they stubbornly linger on. Thus, as Walter Benjamin asserted, the past has not budged – it actually piles up in front of our eyes (2003: 392). In different shapes, and in various conditions, it gathers and constantly sediments into potentially new environments of memory (Bergson 2004; Olivier 2011).

Despite the fact that things clearly do age differently and that their expected life lengths also vary greatly, there is a certain egalitarianism associated with their aging. Thus, and given that also

persistency can be listed among their qualities, things do not discriminate among themselves in their duration. This means that in addition to those "unbroken" things that facilitate continuous, smooth, and sustainable practices, there is a survival of the outdated and stranded. A material past that persists despite being discarded, ignored, and made superfluous – in short, the surviving material redundancy of the past (Fig. 3). Thus, in the notion of a past that sediments and swells in our midst (after Bergson 2004), there is also and always a component of the neglected, the unwanted (Olsen 2010: 166–167). Importantly, this material gathering of the past is largely not subjected to any suspicious plan or ideological script or censorship. It mostly happens in unpredictable ways and according to material trajectories that are beyond or unrelated to human control and intervention and which also allows for less edited or censored memories (Olsen 2010, 2012).

Ruined things were once useful and thus embedded in repetitious practice and infused with lived or habit memory (Bergson 2004). When outmoded and discarded, their lived and habitual significance is lost, while their physical presence, albeit ruined, continues. As such, these broken things survive and gather as the material antonyms to the habitually useful, creating a tension-filled constellation that carries the potential of triggering a particular kind of involuntary memory. Reverberating against the taken-for-granted materiality of habit memory, they become potential agents of disruption, triggering the past in a mode that Benjamin called "actualization" (Benjamin 1999: 473–476). The outdated and stranded give face to forgotten or neglected pasts, to the trivial or embarrassing, to the failed or never completed undertakings, and to the anomalies and the unstable moments. And here lies some of their value or capital: precisely by being redundant and discarded, these things reveal the gaps and crevices in the construction of history as progress, as a continuous narrative; they bring forth the abject memories that are lost in conventional history.

Just by stubbornly being (t)here, the derelict fur farm, the abandoned boarding school, the disconnected radio beacon, or the abandoned fish processing site openly rebuke the conception of history as sequenced, biographical, and progressive. They of course share this persistency and

Modern Ruins: Remembrance, Resistance, and Ruin Value, Fig. 3 Stranded. Redundant Soviet fishing fleet brought to rest in Teriberka, Kola Peninsula, Russia. (Photo: Þóra Pétursdóttir)

opposition with their older comrades. However, being *modern* ruins, and thus somehow closer or at least more familiar, and also through their conspicuous transient mode of being, they enact this resistance – and potential – more effectively than ancient ones. In their own and very positivistic manner, they show that history is not a projected stream leaving the past behind but that it bends and twists in a disorderly manner, interrupting the expectations of the *have been* and the *becoming*. Further, by often being negative features within the contemporary geopolitical order, the ruins of the modern also hold on and make manifest alternative geographies. They bear witness to other cultural or economic landscapes and to past presences in strange places: a stranded English train engine in an Icelandic fjord, a frozen German weather station in east Greenland, and a ruined Soviet missile hangar in Cuba (cf. Jensen and Krause 2011; Burström et al. 2011).

To speak of ruin memories may of course sound like a conceptual contradiction. Abandonment and ruination is usually understood negatively through the tropes of loss and deprivation. Through decay, withering, and corrosion, things are degraded and humiliated, while the information, knowledge, and memory embedded in them become lost along the way. However, without at all ignoring its negative aspects, not to mention the immense human traumas inflicted through its sometimes violent and catastrophic causes, ruination can be seen as disclosure – as a mode of unconcealment and thus a form of recovering memory (DeSilvey 2006). Experiencing an inhabited and well-kept building may not reveal much about the way it actually works, the diversity of materials and technologies that are mobilized to construct and operate it. If not cunningly hidden by design and architectural form, these materials and implements themselves are often absorbed by their tasks; they disappear into usefulness and chains of relations.

Decay, ruination, abandonment, and disposal, however, disturb the routinized and taken-for-granted and produce a defamiliarized landscape (Edensor 2005: 109). Plaster and wallpaper peel off, doors are opened, windows broken, and access provided (Fig. 4). The masked object is unveiled, inside is turned out, and privacy revealed. Ruination becomes a kind of slow-motion archaeology, a self-excavation that exposes the formerly hidden and back-staged. In

Modern Ruins: Remembrance, Resistance, and Ruin Value, Fig. 4 Inside turned out, privacy revealed. Bunk beds in rooming house for female workers at the herring factory in Eyri, NW Iceland. (Photo: Þóra Pétursdóttir)

the destruction process, new meanings may be revealed, meanings that may perhaps only be grasped at second hand when no longer immersed in their withdrawn and useful reality. Moreover, by being released from the chains of use, things themselves become more present; they appear to us in ways not seen before. And perhaps it is in this state of abandoned being, "freed from the drudgery of being useful" (Benjamin 2002: 39), that things' ownness and integrity is released and finally enables them to articulate their own source of signification?

Critical Aesthetics and Ruin Values

A final topic to be explored is how the ruins of modernity are and may be integrated in contemporary cultural processes and how they can fuel discourses of alternative aesthetics and social critique and at the same time enhance social cohesion by providing physical space for critical, marginal, or alternative cultural practices?

One outcome of the modern attitude toward things and materiality is an oppositional hierarchy between, on the one hand, functional and/or aesthetically pleasing things and, on the other, waste – all rubbish we find disgusting, ugly, polluting, and just want to rid of by increasingly more effective systems of disposal and recycling. In contrast to the attitude characterizing our not so very distant ancestors, the main rule of contemporary public aesthetics is purity and neatness, to "tidy up," to clean and repair, or better replace. Waste, including wrecked cars, abandoned buildings, and rusty oil tanks, constitutes an embarrassment and a problem that should at all costs be kept out-of-sight.

Heritage practices may at first be thought of as mediating this opposition, reflecting a care for and attentiveness to the useless and stranded. After all, it is residues such as these on which archaeologists base their entire knowledge of previous societies. More than anyone, however, archaeologists know that the dialectic between the ruin as rubbish and the ruin as heritage is a fragile one (e.g., Burström 2009; Pétursdóttir 2013; Kobialka 2014; DeSilvey 2017). But while surely not all ruins are as capable of becoming heritage, the case is rather that what is conceived of as proper heritage itself is most strongly affected by this aesthetics. The heritage site, the ancient ruin, is often staged, neat, and picturesque, providing visitors with a disciplined and purified space (Edensor 2005: 22, 95) (Fig. 5). Extraneous materials – plants, fauna, debris, and modern materials – all pollutants, are to be expunged, and further decay is staved off through restoration and preservation. Arresting decay, preventing death, of course, has always been the imperative of heritage management. And this, moreover, relates to the wider and equally ontologized modern tropes of sustainability, conservation, and the wish for eternal life in general.

Matched against this aesthetics, it is not hard to see why modern ruins fail. They are withering and crumbling: walls and concrete decompose, and nature intrudes, mingles, and reclaims. Gulls, insects, rats, fungus, scrubs, and trees invade and establish their own ruin ecologies. The previously clear distinction between the man-made and the natural surrounding evaporates. Given the imperatives of the current *Zeitgeist*, where all culture-natures should be neat, healthy, and in balance, where the human body should stay young, fit, and slender, and impairment and death increasingly seems to have become an embarrassment, these ruins make manifest conditions conspicuously at odds with dominant aesthetical, cultural, and political tropes. In their hybrid or uncanny state, they become antonyms of the modern and blur established cultural categories of past and present, purity and dirt, and waste and heritage; in short, they become matter out of place and out of time (Fig. 6).

At the same time, it is precisely this capacity, this rebellious affordance, which provides them with yet another agency and critical potential. Through their difference and disruption, they oppose and rebuke the ideal of seamlessness and tactile sterility and thereby deride taken-for-granted conventions of purity and dirt. Just think of the contrast their presumed disgraceful alteration and disintegration provides to smooth and increasingly regulated urban spaces and their normalized tactilities of domesticated sounds, smells, and sights (Edensor 2005: 57). In fact, it may be argued that the current urge to clean up and

Modern Ruins: Remembrance, Resistance, and Ruin Value, Fig. 5 Staged, neat, and picturesque. The ready-ruined Whitby Abbey, Yorkshire, England. (Image by Colorbox.com)

Modern Ruins: Remembrance, Resistance, and Ruin Value, Fig. 6 Anti-heritage. Abandoned Khrushchev era apartment block in Nikel, Kola Peninsula, Russia. (Photo: Bjørnar Olsen)

reshape cityscapes to make them efficient, tidy, and green is to deprive the city of its essential, ruin-inclusive affordances. As argued by Shannon Lee Dawdy (2010), ruins, such as neglected neighborhoods, vacant warehouses, abandoned amusement parks, and squatter camps, although controversial, may be seen as an integrated part of what we think of as the modern city:

> Looking at the prevailing images of the modern city from the eighteenth to the twentieth century, one would have to conclude that a city would be incomplete and out of balance without ruins and unpoliced zones. These are part of what we desire in a city. (Dawdy 2010: 773).

Also in this sense, ruination may be seen as a kind of return or recovery. However, it is not only a matter of aesthetics or desire but also of social needs and requirements. While modern ruins may be said to manifest or act out a cultural critique through their uncanny, abject being they are to some extent, yet paradoxically, also significant constituents in the reestablishment and maintenance of social order, to Mary Douglas, dirt resembled social disorder (Douglas 1966: 2), and it was through its abolition, through purification, that society and social order could be established. However, as everyone knows, housekeeping is mostly about making things disappear from view rather than disappear all together. Things swept away, flushed, or thrown out are thankfully no longer *here*, but they are unfortunately still *there*. As Bruno Latour (2009) has argued, this relentless strife toward a neat order of things has come to the critical point where we cannot rely on an "outside environment," or an out-of-sight environment, any more. "There is no reserve outside which the unwanted consequences of our collective actions could be allowed to linger and disappear from view" (Latour 2009: 143). Latour (2009) has even traced the rise of modern environmentalism to this growing problem of "lack of outsides."

While correctly construed, however, the relentless sedimentation of modern ruins can be seen as challenging Latour's claim. Their abject being, even in an urban context, produces "negative features" – localized outsides – that, temporarily at least, will accept the unwanted activities and residues of conventional social practices and thus keep them out-of-sight. For example, when a modern enterprise abandons a building, it is not simply left behind, becoming something past and *gone*. The building of course lingers on and is in a way "returned" to unprescribed activities and "informal economies" (Dawdy 2010: 776) (Fig. 7). It is turned into a democratic space of common access – a trash dispenser, a canvas for artists, a home for the homeless, a void for the criminal, and a center for the marginal – a place, or an "inside," for activities generally preferred out-of-sight,

Modern Ruins: Remembrance, Resistance, and Ruin Value, Fig. 7 Returned to unprescribed activities. Domestic house used as waste disposal for (mainly) king crab claws. Teriberka, Kola Peninsula, Russia. (Photo: Þóra Pétursdóttir)

pressed to the outskirts of the social order, enabling opportunities of alternative modes of life (Edensor 2005; Dawdy 2010: 776). In more quotidian and prosaic contexts, the lure of abandoned buildings and derelict structures is probably something most of us have experienced. They provide alternative spaces that support a range of alternative uses: places where windows are for breaking, where common rules do not apply, and the places of numerous first time experiences.

This ambiguous lure is probably also part of the reason why we today see a renewed interest in modern ruins, as exemplified by the urban explorer movement and the fast-growing number of websites, popular and academic books, and papers devoted to this topic. Tim Edensor has even claimed that there is a "turn to ruins" in the social and human sciences, similar to "the craze for ruins in the Victorian age" (2011: 162) – a kind of "Ruinenlust" (DeSilvey and Edensor 2012). However, as little as there was a craze for ruins in the Victorian age, it was in fact very selective and reserved for the few; the interest in modern ruins is still largely a marginal phenomenon, which has, for example, hardly affected heritage charters, or concern. And maybe it is this shared marginality that is the very source of this fascination. In other words, the uncanniness which prevents modern ruins from being enrolled in conventional conceptions of aesthetics, history, or heritage is also what is desired among those who are at odds with these values of the establishment (e.g., Pétursdóttir 2013; Kobialka 2014). Without this otherness and marginality, modern ruins would be less interesting as a fringe and underground phenomenon and, more seriously, also lose their greatest tangible assets with respect to infuse a critical discourse on these values.

Edensor is probably right that the new interest in modern ruins is to a considerable extent due to a current social and political unrest and a resistance toward the often naive assumptions of order and progress in modernist projects (Edensor 2011), in other words, a rejection of grand narratives and big abstract plots through the praise of the immediate but largely ignored residual by-products of these projects. Importantly, however, the ruins themselves should not be seen as simple rhetorical tools, symbols, or patent allegories in this discourse but rather as its very source and drive. They are actively part of the discourse through their "affecting presence," in form of *immediacy* and not only of mediation (Armstrong 1971: 26). And of course, if we understand their agenda correctly, it is not one of domestication or normalization but one of acknowledgment. In fact, subjecting them to sameness would easily bring their own critical voices to silence.

Future Directions

Afterthoughts

The word *ruin* is indeed an ambiguous and contested one. However, at the core of this ambiguity are real and material phenomena that despite being subjected to dominant tropes of cultural ordering also have their own integrity and wealth of affordances, including the capacity to oppose and rebuke these censoring tropes. By their very material presence, modern ruins become untimely reminders of the historical and contingent nature of these tropes and may also trigger involuntary memories of what is marginalized or left out of conventional historical accounts. As such, their "mission" seems to comply well with an underlying and justifying subtext in most archaeological discourses on the recent and contemporary past. That is, due to their multi-vocal and democratic nature, these abandoned things give voice to marginalized social groups and people; they enable other histories and alternative *human* pasts (e.g., Buchli and Lucas 2001; Olivier 2001; Harrison and Schofield 2010).

While there are a number of good reasons, politically as well as ethically, to sympathize with this emancipating perspective, the fact that it is still conveniently restricted to *our species only* calls for some final reflections. That is, despite the many democratic pleas for the marginal and othered, the things or the ruins themselves are largely regarded as mere means to reach something else and presumably more important: neglected cultures and deprived *human* agents

behind these decaying artifacts. The things or ruins themselves are little but things-for-us, reduced to what Heidegger once termed "Bestand," by which their manipulative being as "standing reserves" for us is what largely remains (Heidegger 1993; Introna 2009; cf. Olsen 2010: 82; Pétursdóttir 2014).

A radical implication of the position explored in this entry is that modern ruins are also valuable in and of themselves: as physical entities with a rightful presence in the "order" of urban or rural landscapes. This, importantly, also includes their right not to be meaningful in the dominant interpretative sense where meaning is often conflated with derivative meaning: meaning for and from us. In abandonment and ruination, things are freed from chains of use value; they are allowed to be themselves and to indulge in their own material trajectories and companionships (Fig. 8). Surely this releasement confronts our customized habit of dealing with things as goods, as tamed domesticated possessions, or as peepholes to a bygone past. Familiar things suddenly appear to us in ways never noticed, become pestering and alien, exposing some of their own unruly thingness. Acknowledging this particular integrity and affordance of modern ruins, by being exposed to their radiation of immediate and anti-intellectual meaning, may also help preparing the ground for another and yet seemingly unlikely possibility: that they themselves are the source of their own signification (cf. Benso 2000: xxvii; B ennett 2010: 108).

Modern Vessel Archaeology (Iron and Steel Wrecks)

Michael McCarthy
Department of Maritime Archaeology, WA Museum, Texas A&M and NDU (Fremantle), Fremantle, WA, Australia

Introduction

In 1964, the State of Western Australia protected all pre-1900 shipwrecks whether of wood or iron, propelled by sail or steam. In 1972 the acknowledged "founder" of maritime archaeology – a student of wrecks from the classical era – used the example of American Civil War vessels to attest to "the value of archaeological research on ships recent enough for photographic records to be available" (Bass 1972: 10). One was the steam-driven wooden-hulled "ironclad" USS *Cairo* (1861–1862). In the following year, another Civil War vessel the iron-hulled USS *Monitor* (1862–1862) was declared the United States' first National Maritime Sanctuary (Broadwater 2012). Just a few years later, the notion that "modern wrecks" were significant entered a previously skeptical European maritime archaeological psyche when the editors of the British-based maritime archaeological journal the *International Journal of Nautical Archaeology* carried news of the USS *Monitor* research (Watts 1975). Today iron, steel, and steamship wrecks form a significant percentage of many nation's underwater cultural heritage. When Australia proclaimed its national shipwreck legislation in 1976, for example, nearly one third of all the wrecks protected around the nation were iron-hulled sailing ships and steamers. One of the first also was the steel-hulled Japanese Submarine *IJN I 124*, (1922–1942). It had a restricted zone prohibiting entry without a permit and (as the parliamentary debates show), and it was protected more for social and political considerations than for its archaeological potential. One very modern example, and one where social implications also predominate, is the c. 220-m-long steel freighter *Edmund Fitzgerald* (1958–1975). Declared a maritime archaeological site under the terms of the *Ontario Heritage Act*, its significance to Great Lakes communities and to the relatives of those lost is undoubted. Having disappeared with all hands for decades, in remaining virtually untouched as a result – escaping the salvors and the ship-breakers who have long since claimed their more accessible shallow-water counterparts – *Edmund Fitzgerald* is inexorably becoming the only intact example of its type. To students of mid-to-late twentieth-century technology, shipping, and crewing practices, its full archaeological and technological significance will not be realized for generations to come nonetheless. There are many other examples globally, and the archaeological worth of these "unique" wrecks is escalating as the years pass.

Definition

Though relatively recent– post the nineteenth-century Industrial Revolution – iron, steel, and steam shipwrecks can provide, through archaeology, information that is not available in the accepted accounts, in archives, or in oral histories. These data can be technical, technological, economic, social, and behavioral. These "modern" wrecks can also be the catalyst for a wide range of associated historical, economic, and anthropological studies, with their finding and the analysis often providing a raison d'être and focus for those studies.

As with their older counterparts, some "modern" vessels constitute the world's "shared maritime heritage." A good example is the hundreds of Japanese midget submarines lost or abandoned around the globe in WWII. Not only did a recent study reveal social, historical, and technical details not available previously, but it also showed the extent to which these vessels were socially and emotionally shared by Japan and by every nation in whose water they lie (Delagado et al. 2016).

In some cases, there will be more than two nations involved, especially where a range of countries were involved in a particular event, e.g., the many vessels lost in the various phases of the construction of the Panama Canal. Another example is a suite of French, British, and

Australian iron and steel warships and other vessels (barges, freighters, and small troop-carrying boats) sunk by Turkish forces during the Dardanelles campaign in WWI. One of this group, the lost submarine *AE2* (1913–1915), became a focus for Turkish interests seeking to raise it in celebration of the successful defense of their homeland against invading enemy forces. *AE2* is also a prime example of a case where shared cultural heritage is valued and managed by two once warring nations acting in concert. There will be many similar examples across the globe.

The modern maritime archaeological powerhouses of Asia have developed extensive archaeological programs, and in some cases, modern wrecks are the subject of academic interest. The mid-1990s investigation of iron- and steel-hulled steamship wrecks in the Lakshadweep Islands in the Arabian Sea off India is an example of this process (Gaur et al. 1998). These countries and many of the signatories to the UNESCO convention on the Underwater Cultural Heritage, which protects all sites a century or more old, will inexorably continue this process. Of special regional and national interest will be those iconic modern ships of commerce and war that are representative of defining civil wars and modern struggles for political, social, and economic freedom. A prime example is Sun Yat Sen's SS *Zhongshan Jian* (1910–1938), which was raised with many artifacts in 1997 and excavated to become a centerpiece of its own Museum in Wuhan. One interesting example, albeit one far removed geographically from its chief stakeholders, is the Confederate commerce raider CSS *Alabama* (1862–1864). It was sunk by USS *Kearsage* off Cherbourg, France. A very rich wreck, with considerable social significance to both sides of the American Civil War, armaments, and other objects have been raised in concert with French specialists in readiness for an exhibition in the USA. At the other end of the spectrum is the relatively sterile SS *Conch* (1892–1903), a very early shell oil tanker and popular dive site. Here, as in many other instances across the globe, a modern wreck's value for dive tourism now serves to help protect the site from further salvage (Muthucimnerana 2007). A rare example of the early tankers, SS *Conch* is also of increasing historic and socioeconomic relevance with connotations for an oil-dependent world. In that respect, *Conch* is part of the "global maritime heritage."

The Development of the Discipline

In tracing the antecedents of modern ship archaeology, two defining modern wreck studies occurred in 1983. One was the corrosion assessment of the massive steel-hulled USS *Arizona* (1915–1941) at Pearl Harbor in Hawaii (This is ongoing, e.g., Foecke et al. 2010). The other was the archaeological-behavioral study of the tiny iron-hulled SS *Xantho* (1848–1872). Having commenced with a pre-disturbance biological and electrochemical (corrosion) analysis by diving conservators, followed by the application of anodes to help preserve the hull and its unique ex-Royal Navy gunboat engine, the latter study firmly cemented the place of diving corrosion scientists in iron (and steel) ship studies and in modern maritime archaeology. Conversely the de-concretion and disassembly of the *Xantho* engine was treated as an excavation in its own right, performed by the conservators yet supervised by the archaeologist in charge – posing questions, assisting and closely observing throughout, and revealing new information about the technology and also behavior of those who owned and operated the vessel (Veth and McCarthy, 2001). That the engine can now be turned over by hand, attests to the successful application of conservation expertise and the essential role conservators (including diving conservators) have in successfully managing modern wrecks. Another development in the *Xantho* instance was the production of an archaeologically based working model of the engine. Commonplace in the study of the hulls and rigging of wrecks of ancient sailing vessels where plans and descriptions are sparse – or nonexistent (as was the case with the engine from the *Xantho*) – the value of working models based on the archaeological drawings taken from "modern vessels" has been clearly demonstrated. *Xantho* is also a prime example

where "public archaeologists," i.e., those employed by and acting on behalf of an institution, have an overarching obligation to the people inhabiting and visiting the region it serves – in this case a museum. In this instance, traditional reporting methods such as technical reports, articles, books, and websites are, of necessity, augmented by works aimed at that broad spectrum of society that frequents the museum in which the objects are housed and interpreted (McCarthy 2017). Part of the Western Australian Museum's "wreck access," program *Xantho* is an underwater "museum-without-walls," while its engine features in a special gallery (Figs. 1 and 2).

Modern Vessel Archaeology (Iron and Steel Wrecks), Fig. 2 SS *Xantho* engine in 2017, appearing in an underdeck scene at the Western Australian Shipwreck Museum (K. Edwards)

Modern Vessel Archaeology (Iron and Steel Wrecks), Fig. 3 SS Xantho Engine in 1985 on the seabed (P. Baker)

The "in-laboratory" excavation of the Confederate submarine *H. L. Hunley* (1863–1864) along with the human remains and personal effects of the Civil War dead contained within (Fig. 3) proved another milestone in modern vessel archaeology. This forensic exercise together with the recording, analysis, and exhibition methods utilized to bring the project to the general public (including working models and computer graphics of the cramped interior) became the benchmark in "post-raising" archaeology, conservation, and presentation method (Mardikian et al. 2009).

Where excavation is indicated, or can be supported by the required conservation expertise and the long-term commitment of staff and resources, limited excavation is most often the result at modern wrecks. Enclosed compartments help reduce the negative aspects of excavation (e.g., seabed scouring, accelerated degradation) especially where the process can be quarantined to one discrete section of a site. An example is the fieldwork conducted at the iron-hulled SS *City of Launceston* (1863–1865) involving a full archaeological survey, corrosion and biological studies, and the testing by excavation of one discrete accommodation area, recovering but a few objects and leaving all other compartments and their contents untouched (Anderson 2009). This is perhaps as it should be. For as observed by one of the better known practitioners, "modern" shipwreck conservation needs can "last well beyond the tenure of many directors of museums and their employees, as well as that of corporate sponsors" (MacLeod, 2016).

Another trend in modern ship archaeology has been toward thematic studies linking sites of similar type and purpose. One example is the Civil War blockade-runner type, with the Confederate paddle steamers *Denbigh* (1860–1865) and *Mary Celestia* (1861–1864) among the best known. Another is the study of the American river steamboat, e.g., *Heroine* (1832–1838). Another relatively recent trend includes managing shipwrecks of all types and ages as part of the "cultural landscape" of a place or region. Here a wreck may not be excavated at all but is archaeologically surveyed, assessed, and valued as an integral part of a far wider suite of natural and cultural sites (see Ford 2011). Such a large collection of sites in close proximity can also be of ongoing social and economic value to the communities in whose water they lie, thereby extending the "landscape" into modern times.

A prime example is the well-known and much-visited wrecks of Chuuk (Jeffery 2006). These are also the focus of studies essential in understanding the many thousands of wartime wrecks that will inexorably release oils and other toxic substances into the water column.

Notable early examples of modern wreck studies are *Holland I* (1901–1913), RMS *Titanic* (1911–1912), and the German battleship *Bismarck* (1939–1941). All occurred in 1985. While *Holland* resulted in the preservation and presentation of a seminal, groundbreaking "type," *Titanic* and *Bismarck* provided a great deal of additional information about how the two ships sank and solving a number of ongoing mysteries. By the quality of their recording, they also set an early benchmark for the then burgeoning discipline of non-disturbance deepwater shipwreck analysis or archaeological survey by remote sensing. Remote-operated vehicles and manned submersibles, together with remote-sensing equipment such as magnetometers and side-scan sonar, are now commonplace in finding, examining, and analyzing wrecks. These and others following are characterized by what is essentially an expert "remote site analyst" or "archaeological surveyor" directing activities and operating at considerable distance from the wreck itself.

The 2008 examination of the WWII adversaries HSK *Kormoran* and HMAS *Sydney*, in over 2000 m of water off Shark Bay in Western Australia, led to a circumstance where the material evidence on the seabed became *the* essential factor leading to a forensically based resolution of the vast majority of the 67-year-old mysteries and controversies surrounding the battle. The archaeological evidence also helped attest to the veracity of the much-maligned German victor's report of where the battle took place and what occurred after the opening salvo. As an indication of the rapid development of both deepwater expertise and of 2D and 3D recording method in both shallow and deep water, these two wrecks were revisited in 2015 with astounding results. These include over half a million very high definition images and video which was the result of the simultaneous deployment of two ROVs acting in concert each fitted with a very large number of still and video cameras and a similar number of lights. Here for the first time, a series of electrochemical, biological, and other tests were able to be conducted by a large range of scientists on two modern wrecks, lying relatively close to each other and where variables such as date lost, salinity, oxygen levels, depth, marine life, etc. are controlled. Many samples, from the seabed and rusticles from each wreck, were recovered from both sites. Studies are ongoing and will appear in many technical journals (McCarthy 2016) (Fig. 4).

SubMarine Explorer (1864–c.1875) (Fig. 5) is subject to a large tidal range and is in a place where wrecks rarely survive due to their increased

Modern Vessel Archaeology (Iron and Steel Wrecks), Fig. 4 Hunley conservator Paul Mardikian with H.L Hunley at the Warren Lasch Conservation Center. Photo Grace Beahm, Post & Courier (with permission)

Modern Vessel Archaeology (Iron and Steel Wrecks), Fig. 5 The inverted bow of HMAS Sydney. It is being lit by one ROV, photographed by the other and both are streaming video and still photographs from an array of 10 cameras

vulnerability to both natural and human forces. Intended as the Union reply to CSS *H. L. Hunley*, it was launched too late for the American Civil War and was sent to the Panamanian pearl fishery where after astounding successes, it was abandoned in the Pearl Islands and then lost to living memory. A limited excavation of the vessel's bilge and the detailed inspection and analysis of its internal configuration, fittings, and fixtures supplemented the relatively sparse detail found in the archives. This research led not only to the study of the development of the vessel and its groundbreaking submarine technology but also to a study of its builder, its people, and to those allied and associated matters that any investigating maritime archaeologist working in the historical and industrial period is invariably drawn subsequent (or prior) to an archaeological survey, site analysis, or excavation. In this instance, it was to metallurgy and iron founding: the American Civil War, German immigration into the USA, the ancient Panama pearl fishery, the unrecognized advent of the "bends" or decompression sickness in the underwater environment, and much more (see Delgado 2012). Though much had been written about these various subjects, more had been learned as a result of the *SubMarine Explorer* study. As was the case with *Xantho*, the anomalous remains on the seabed also led to the investigation of the role of an innovative entrepreneur and to a study of the premature use of technology in industry in a "frontier" setting. Of additional import, by virtue of the policy of social inclusion evident throughout the study, *SubMarine Explorer* has proved to be a catalyst for an enhanced Panamanian appreciation of their extensive modern maritime heritage post better-known Spanish-colonial and "pirate" eras.

Because those with iron and steel hulls are not affected by shipworm and because they are relatively recent, many modern wrecks often remain highly visible. For that reason, they have also become a major part of the world's wreck access programs, underwater "wreck trails," or "museum-without-walls" presentations, for example, the wartime wrecks of Coron Bay in the Philippines, Bikini Atoll, Chuuk (Truk Lagoon) in the Pacific, the Dry

Tortugas in Florida, Full Fathom Five National Marine Park in Canada, the many NOAA Sanctuaries, world heritage-listed Papahānaumokuākea National Monument, Rottnest Island in Australia, and Scapa Flow in Great Britain, to name a few of the better known. In heralding another important direction, there are many wrecks in flora and fauna sanctuaries, such as the marine parks mentioned above. Occasionally, as at SS *Omeo* (1858–1905), an individual wreck in very shallow water at Coogee near Fremantle has become the focus for the development of an underwater park with underwater sculptures and other attractions. At this and the many facilities mentioned above, the visitor is presented with interpretive (above and underwater) material both on site, on websites, and in social media (Fig. 6).

In many cases, the wrecks have become an educational "hook" or catalyst, in effect tools – educational transports – seamlessly leading the viewer into a greater appreciation of the history and events that transpired often into the underlying economics, technology, work practices at sea, entrepreneurial activity, society, and its mores. For the academic, there are also numerous anthropologically based studies into wrecks or a suite of wrecks of the modern era popular in some maritime archaeological circles (e.g., Gould 2010). These are also many examples of extensive site-specific analyses of the ubiquitous nineteenth-century sailing barques and ships, e.g., *Glamis* (1876–1913) in the Grand Cayman Islands, Jamaica (Ho 2004), and *Sepia* (1864–1898) off Fremantle. While the former concentrated on the technology, the history, and comparative studies, the latter focused on a limited test excavation designed to examine loading methods, colonial trade, and the survivability of cargo (Souter 2009). Over the course of many studies such as those mentioned above, commonalities were observed for iron and steel wrecks. One fundamental principle is what has become known as the "waterline theory of iron ship disintegration" illustrating that an upright iron or steel ship will invariably settle on a seabed of soft sediment down to the waterline (Riley 1988). A major manifestation of this phenomenon occurs in deep- and shallow-water "ship graveyards" into which many vessels that escaped wrecking or the ship-breaker were consigned. As a global phenomenon these provide an opportunity for a wide range of comparative studies and public interaction (Richards

Modern Vessel Archaeology (Iron and Steel Wrecks), Fig. 6 SS *Omeo* a very popular wreck, now at the center of the Coogee Maritime Trail. WA Museum

2008). Not all are underwater. "The Purton Hulks," a group of around 80 wrecks, for example, lie along the banks of the River Severn surrounded by grass, all accessible by scholars and picnicking families, adults, and children alike. These are a prime example of the potential social, educational, and recreational value of the modern wreck.

Finally in progressing from the shallows and the shore, another significant development in modern ship archaeology and site analysis has been the increasing depths at which wrecks are being accessed by divers. As an example of this, at the 1985 practical and theoretical iron and steamship seminar held during the SS *Xantho* excavation, the deepest wreck described was but 30 m. At a follow-up seminar held two decades later, it was in excess of 100 m. This was due to the advent of "technical diving" (open-circuit mixed gas and closed-circuit rebreather) methods and their becoming commonplace across the globe. To an extent, this mirrors the arrival of the scuba tank on the recreational scene 30 years earlier – ushering in a new era in study, analysis, archaeological survey, excavation, conservation, and presentation of modern iron and steel ships. In utilising a combination of geophysics, including multibeam sonar, ROVs and technical divers to examine 76 shipwrecks including 22 vessel sunk during the Battle of Jutland in 1916, Innes McCartney and his teams have taken modern vessel archaeology to yet another level (McCartney 2016).

Modern World: Historical Archaeology

Charles E. Orser Jr.
Department of Anthropology, New York State Museum, Albany, NY, USA

Introduction

Beginning in the 1990s, a number of historical archaeologists began using the term "the historical archaeology of the modern world" to define their research. Their use of this term was designed to refine the meaning of "historical archaeology" to refer to a specific topic of investigation, the archaeology of post-Columbian history, or sites dating to after about 1500 CE. Since then, the term has been used in at least two ways, as the archaeology of a particular period of history, and as an archaeology specifically designed to constitute a critique of modernity.

Definition

Scholars in diverse fields disagree about the precise meaning of "modernity," but when historical archaeologists write about it they typically mean the post-Columbian, or post-1500 CE world. Many historical archaeologists equate modernity with European expansionism beginning with the Portuguese and Spanish voyages of conquest and terminating at the present. This understanding, however, does not preclude the presence of "multiple modernities," the myriad sociocultural environments that may have had little or nothing to do with European interaction, but which existed in parallel with the European world.

The concept of an archaeology of the modern world developed in the 1970s because of two prominent definitions of historical archaeology. The first, offered by Robert Schuyler (1970: 84), defined "historic sites archaeology" (a specialized term then also used for historical archaeology) as "the material manifestations of the expansion of European culture into the non-European world starting in the fifteenth century and ending with industrialization or the present depending on local conditions." Shortly thereafter, James Deetz (1997: 5) provided a similar definition of historical archaeology: "the archaeology of the spread of European culture throughout the world since the fifteenth century and its impact on indigenous peoples." Some archaeologists today approach both definitions with caution believing that Schuyler and Deetz put too much emphasis on Europeans. They believe that the argument implicit in these definitions is that indigenous peoples only reacted to European culture, or, to state it differently, that the transference of objects and ideas was only one directional, from Europeans to indigenous peoples. Other

archaeologists believe to the contrary that the Schuyler/Deetz definitions highlight an important historical process that has affected the way the world has developed since Europeans began their global efforts to colonize, exploit, and control the non-European world.

The perspective that historical archaeology involves the investigation of the post-Columbian world, however, represents a narrow view of the field. A broader understanding is that historical archaeology includes all research that uses archaeological and historical sources of information in relatively equal proportions. These sources can include ethnographies, personal memories, ancient texts, inscriptions and drawings on walls, photographs, transcriptions of oral testimonies, and just about any other material that can provide information about past lived experience. This broader definition thus encompasses the research of Egyptian, classical, medieval, and other archaeologists who regularly employ non-excavated materials in their research. The broadness of this definition is confusing, however, because all archaeologists – even those studying precontact indigenous cultures – might be considered historical archaeologists because they regularly rely on the written works of other archaeologists, colonial missionaries and explorers, and professional field anthropologists to enrich their understanding of ancient ways of life. As a result, most archaeologists who self-identify as historical archaeologists tend to use the more narrow definition of their field, and concentrate their efforts on post-1500 CE history.

Two variants of the historical archaeology of the modern world developed as archaeologists became increasingly comfortable describing their research in terms of modernity. To avoid confusion, "global historical archaeology" may be used to refer specifically to post-Columbian historical archaeology that usually begins with contact situations that involved indigenous cultures and Europeans (e.g., Hall 2000). This kind of archaeology is most consistent with the Schulyer/Deetz definition. "Modern-world archaeology," on the other hand, is a term used to refer to an archaeological critique of modernity, largely focusing on the material and cultural manifestations of colonialism, capitalism, Eurocentrism, racialization, and other entwined processes that were practiced after about 1500 CE and which continue to affect the world's peoples today (Orser 1996).

A primary research topic of modern-world archaeology is the process of becoming modern, with the four processes noted above being a central focus. These four processes, which were put into operation in the world after 1500 CE – by various cultures and at different times – are tightly interlinked and coterminous. The conjunction of these processes provides both the unique character of the modern era and the rationale for investigating it using the multidisciplinary tools and approaches of historical archaeology.

Key Issues and Future Directions

Archaeologists of the modern world do not believe that historical archaeologists should ignore non-European peoples; such a position runs counter to the theoretical foundations of anthropological archaeology. Labeling the archaeology of the modern world Eurocentric – because of its concern with the power and reach of post-1500 CE European nation-states (including the United States) – is an inaccurate oversimplification.

Both global historical archaeology (defined by era of interest) and modern-world archaeology (defined by era and the critique of modernity) are concerned with the myriad linkages between past and present. An interest in the process of modernity, however framed, makes the archaeology of recent history relevant to scholars concerned with transnational geopolitics, global emancipation, and multicultural understanding.

One great potential of the archaeology of the modern world stems from the archaeologists' ability to conduct multiscalar analysis. Archaeologists can examine lived history at different scales because of the richness and diversity of the extant sources. The inspiration for this line of inquiry stems from the research of French historian Fernand Braudel (1972). Braudel saw history as involving three processes: short-term events (e.g., events, individuals; which he called *evenements*), medium-term structures (e.g., social and economic history, regions, worldviews;

conjonctures), and long-term structures (e.g., history of civilization, long-term trends; the *longue dureé*). These processes, though they have the appearance of relating only to time, also have significant spatial meaning. The examination of the short term might involve specific individuals and unique events, but these individuals and events had to occur within discrete physical settings. Given this materiality, Braudel's concepts thus have tremendous application to the archaeology of the modern world. The excavation of a house foundation and yard inhabited by a specific person or family might constitute the short term, and the medium term might involve a broader analysis of the neighborhood during the time the family occupied the dwelling. The *longue dureé* might involve an analysis of the entire historical era into which the family – and people like them – operated. To use the enslavement of Africans as an example, the short term could be the excavation of a cabin site on a colonial plantation in Jamaica, the medium term could be the analysis of the slave regime on the island, and the *longue dureé* might involve the entire history of African enslavement in the British Atlantic world.

Globalization is one topic that is especially amenable to analysis as part of the archaeology of the modern world. Globalization is a huge subject with myriad definitions, but one easy way to envision it is as "a state of the world involving networks of interdependence at multicontinental distances. The linkages occur through flows and influences of capital and goods, information and ideas, and people and forces, as well as environmentally and biologically relevant substances (such as acid rain or pathogens)" (Keohane and Nye 2000: 105). This definition stresses two key elements. It promotes the idea of multiscalar analysis because the various linkages have local, regional, and transcontinental expressions. At the same time, the definition does not denigrate the large-scale networks of interaction that existed before 1500 CE, but simply argues that modern-era globalization was enacted on a scale that linked together vastly different peoples across huge distances. These cultures would never have been in contact without globalization. The definition also creates space for the analysis of environmental degradation and biological change in the analysis, topics that have had archaeological significance for years and which continue to have profound importance today. The addition of contagion is especially important for post-Columbian history because it creates space to investigate the transference of disease as a result of cultural contact.

Archaeologists can investigate modern globalization using diverse sources of information. Most pointedly they can employ their special skills in excavation and artifact analysis, modes of investigation not available to scholars in other disciplines. Much archaeological research will undoubtedly concentrate on the local recontextualizations of introduced material objects as part of a process called glocalization.

Glocalization refers to "the interpenetration of the global and the local resulting in unique outcomes in different geographic areas" (Ritzer 2003: 192). Glocalization is a process well studied by cultural anthropologists, and an awareness of the process in archaeology has led to the writing of "alternate histories" of the modern world, histories that can be used to promote human rights, cultural awareness, and sensitivity to the wishes and worldviews of people throughout the world.

Archaeologists of the modern world are uniquely situated to examine the historical and material roots of globalization and glocalization using their unique sources, including excavated artifacts, information revealed in buried structures, and a diverse range of textual materials. They can chart the initiation, growth, and eventual termination of cultural interactions in the post-1500 CE world using Braudel's ideas about space and time as a starting point. Through this research, archaeologists of the modern world can learn about our own times and gain fuller understandings of their historical and cultural roots.

Molluscs (Invertebrates): Analyses in Environmental Archaeology

Canan Çakırlar
Groningen Institute of Archaeology, Groningen University, Groningen, The Netherlands

Introduction

Due to their variable but generally high inorganic content, shells of the phylum Mollusca constitute one of the most durable categories of biogenic finds in the global archaeological record. Mollusc shells are omnipresent and often highly visible in the archaeological contexts across the globe, with the rare exception of wet-preserved contents of acidic bog contexts. The nature and quantity of archaeological mollusc shells vary tremendously among sites, chronological periods, and geographic areas, from 125 ka BP sites associated with early modern humans in eastern Africa (Stinger 2000) to elaborate ornaments from Pre-Columbian Colombia (Carvajal-Contreras 2011). Depending on the geographic area and research question, investigations may focus on molluscs of terrestrial, freshwater, or marine origin, and they may focus on molluscs that were exploited as food resource or as raw material in artifact manufacture. Because mollusc shells archive changes in their ambient environment as they grow incrementally (Richardson 2001), archaeological mollusc shells can become subjects of independent or integrated studies of paleoenvironmental conditions.

Definition

The analysis of mollusc remains from archaeological contexts is an integral part of environmental archaeology and zooarchaeology. Both human-modified and naturally occurring mollusc remains can be subject to molluscan analysis in archaeology. The nature of archaeological mollusc evidence can be alternatively classified in terms of different molluscan taxa and habitats.

Molluscs (Invertebrates): Analyses in Environmental Archaeology, Fig. 1 Examples of mollusc shells that occur frequently in archaeological contexts (1) Scaphopoda, *Dentalium* shell; (2) Gastropoda, terrestrial (land) snail; (3) Gastropoda, Cypraeidae, "cowrie shell"; (4) Gastropoda, *Patella rustica*; (5) Cephalopoda, *Sepia* sp., "cuttlefish bone"; (6) Bivalvia, *Chamelea gallina*

Archaeological molluscs of terrestrial origin consist of gastropods and are colloquially dubbed as land snails. Molluscs originating from marine environments mainly comprise both gastropods (e.g., whelks, topshells, limpets) and bivalves (e.g., clams, oysters), but remains of other classes of marine molluscs such as cephalopods (typically cuttlefish bones) and scaphopods (typically *Dentalium* shells) may also occur commonly in certain contexts (Fig. 1). Artifacts made of molluscs, molluscs that represent food, and naturally occurring molluscs are usually handled separately from each other.

The study of archaeological mollusc shells is increasingly commonly referred to as "archaeomalacology" since the beginning of the twenty-first century (Bar-Yosef Mayer 2005; Çakırlar 2011). The analysis of mollusc shells tackle a seemingly unlimited range of anthropological and paleoenvironmental issues (Claassen 1998). Analytical methods of archaeomalacology include taxonomic identification, sclerochronology (incremental analysis), taphonomy, biometry, quantitative estimations of abundance, ubiquity, dietary contribution, and habitat construction, as well as experimental archaeology of artifact technology and ethnoarchaeology. Common themes in the study of archaeological molluscs include dietary reconstruction, long-distance contact, artifact technology and use, symbolic uses of shells pertaining to belief systems and representation of socioeconomic class and status, industrial activities, seasonality of food acquisition, and human exploitation pressure on marine ecosystems. Theoretical approaches to archaeomalacology have been largely dominated by optimal foraging concepts on the one hand and culture-historical approaches on the other.

Historical Background

The study of archaeological molluscs has developed as a distinct field within environmental archaeology (Brothwell and Higgs 1969) and zooarchaeology (Grigson and Clutton-Brock 1984). J. Evans' work on land snails in the context of British archaeology has played a key role in the recognition of mollusc remains as a source of paleoenvironmental information in the UK (Evans 1972). With the rise of Middle-Range Theory in archaeology and New Archaeology, the field developed rapidly in North America, focusing mostly on developing methods to decipher the meaning of gigantic masses of mollusc remains in coastal shell remains for post-Pleistocene adaptations of hunter-gatherer-fisher groups. The historically important study of Ertebølle culture in prehistoric northwestern Europe has also benefited from these

international developments in terms of the methodological aspects pertaining to related molluscan evidence.

One landmark in the history of archaeological mollusc analysis is a pilot study that used the light stable isotopic (carbon and oxygen) compositions of archaeological *Cerastoderma glaucum* (lagoon cockle) incremental biocarbonate in estimating shellfish gathering seasonality (Shackleton 1970). Further methodological advancements in applications of sclerochronology (analysis of ontogenic incremental shell patterning) and shell ecomorphology – relating shell size and shape to molluscan habitats – continue to contribute to the methodological development of the field (Michel et al. 1992).

Key Issues/Current Debates

Studies of archaeological mollusc shells contribute to current debates concerning a number of key issues in archaeology, ranging from the evolution of shared symbolism in recent species of *Homo* (e.g., D'Errico et al. 2005) to the reconstruction of past human impact on marine resources to serve as a baseline for conservation efforts (Marelli and Arnold 2001).

Some of the most tangible lines of archaeological evidence related to the biological and cognitive evolution of recent *Homo* sub/species occur in the form of mollusc shells. Perforated *Nassarius* shells from human encampments dating back to c. 80,000 years ago constitute some of the earliest ornaments used by humans in Africa (D'Errico et al. 2005). The anthropogenic origin of the perforations was established by experimental work on modern shells. Taphonomic observations using SEM microscopy showed use wear, indicating that perforated objects were strung and probably worn as personal ornaments. Recent well-dated finds indicate that Neanderthals in Europe also manufactured and used perforated and ochre-dyed marine molluscs (Zilhão et al. 2010). The power of such studies in convincing others to see the tangible imprints of hominid symbolism comes from their vigorous use of combined actualistic and stratigraphic research. Experimental work and comparative SEM studies of results have also been of great use in reconstructing the manufacture process and utilization of mollusc shell objects of symbolic value in more recent periods, for example, in aboriginal Australia (Szabó et al. 2007).

Although claims about the significance of the role that marine molluscs played as a food resource during *Homo sapiens*' dispersal out of Africa – together with other marine food resources enabling them to explore coastal routes – have sparked some attention (Stinger 2000), for the time being, evidence for intensive exploitation of molluscs by early modern humans can only be substantiated for the later Palaeolithic phases in Southern Africa (Middle Stone Age, c. 50 ka BP) (Klein et al. 2004). Intensive exploitation of marine molluscs, however, does not become evident until the widespread appearance of shell middens during the Late Pleistocene and Early Holocene on almost all coasts of the world, from Japan to Denmark and Peru (Waselkow 1987). Despite the amplitude and ubiquity of mollusc remains at these and subsequently formed shell middens, whether molluscs constituted, in simplest terms, a dietary staple or supplement for coastal groups who occupied them is still debated (Fa 2008).

The various methods developed to assess the dietary role of molluscs for past human groups, as well as other issues pertaining to shell midden archaeology, such as site duration and seasonality, have also been received with mixed criticism and praise. For example, Claassen (1998: 49) has called for caution toward the common use of decrease in mean shell size as a proxy for declining survivorship in mollusc populations due to human exploitation, arguing that the method dismisses other factors – including pressure from predators other than humans – as potential causes for changes in shell size. Similar debates on methodology have gradually led to the advancement of the analytical procedures used to investigate archaeological molluscs, leading to the more common integration of actualistic research on geographically coherent modern mollusc populations as a means of modeling past human behavior relating to shellfish use.

Molluscs (Invertebrates): Analyses in Environmental Archaeology, Fig. 2 A sample of crushed *Hexaplex trunculus* (Muricidae) snails from Late Bronze Age Troy. The shells are crushed in the process of dye manufacture

Other lines of actualistic research, such as ethnographic observations of forager groups, have greatly added to our understanding of the formation of mollusc evidence (Meehan 1982). To these, we can add the contribution of experiments conducted by Ruscillo (2005) that shed light on the formation of the mollusc evidence in detecting origins and scale of a dye industry in the Mediterranean region that used the purple substance secreted by Muricid snails' hypobranchial gland as raw material (Fig. 2). The so-called murex or purple dye industry is mentioned in the Old Testament and by Classical authors. The antiquity and nature of ancient dye manufacture using Muricid snails is a frequently visited issue also in South American archaeology.

International Perspectives

Current international research on archaeological molluscs can be summarized into three broad categories: scholarship that focuses on archaeological molluscs as artifacts, molluscs as dietary remains, and molluscs as climatic archives. While artifacts made of molluscs tend to receive more scholarly attention in parts of the world where molluscs played a more visible role in the symbolic world of past cultural groups (e.g., Pre-Columbian Meso-America), in other parts of the world where shell middens are abundant (e.g., Denmark, Japan, California), archaeological molluscs are commonly investigated to test hypotheses relating to the adaptations of hunter-forager groups. Studies that consider the role of molluscs as a food resource in past farmer-herder societies are significantly less common. In studies of post-Neolithic, sedentary societies, mollusc remains (sometimes including fossil molluscs) are commonly used to map long-distance exchange patterns (e.g., Red Sea shells in Bronze Age Mesopotamia), ritual behavior (e.g., mollusc shells adorning the dead), symbolism, and artifact technology. If the variability of the prominence of these two research foci is in part determined by the nature of evidence that varies from one region to the other, it is also in large part dictated by dominant regional academic traditions. Although the exploration of archaeological molluscs, especially land snails, as vessels of past environmental conditions has left a significant impact on the archaeological traditions of some countries like the UK (Evans 1972), this resource has gone almost completely unnoticed in others.

The Archaeomalacology Working Group of the International Council for Archaeozoology (ICAZ) has been fundamentally instrumental in bringing together the multiplicity of international perspectives since its establishment in 2002. Admittedly, proceedings and newsletters of the group (Bar-Yosef Mayer 2005; Çakırlar 2011) testify to its limited success in embracing shell midden and sclerochronological research.

Future Directions

The field of sclerochronology has witnessed a huge leap forward in the recent decade (Schöne and Gillikin 2013), but it unfortunately remains almost entirely unrelated to anthropological (primarily forager behavior) and paleoenvironmental research encapsulated by archaeomalacology. The next decade will hopefully bring along effective communication between

archaeomalacology and sclerochronology that will create important opportunities for application in both fields. For the advancement of the analysis of mollusc artifacts, there is ample room toward the under-explored sources of ethnography and use-wear studies. The archaeology of mollusc remains would also benefit from more effective integration with ichthyoarchaeology especially in forming firm baselines for research in conservation biology.

The above-mentioned lines of research, with their differing foci on artifactual mollusc remains, dietary mollusc remains, and mollusc remains as paleoenvironmental proxies, are likely to prevail and progress as largely independent specializations. At the same time, recent studies give clues toward the likelihood that greater shared ground is to be found across the existing "subdisciplines" with interest in archaeological molluscs. This is evident, on the one hand, in the greater emphasis put on the biological and environmental properties of worked and used shells, and in the attention paid to the taphonomy of mollusc remains considered to represent dietary activities on the other, leading to better understandings of, for example, site formation processes. Such developments can only be beneficial for the progress of the field as a whole.

Molluscs (Isotopes): Analyses in Environmental Archaeology

Amy Louise Prendergast[1] and Rhiannon Elisabeth Stevens[2]
[1]Department of Archaeology and Anthropology, University of Cambridge, Cambridge, Cambridgeshire, UK
[2]McDonald Institute for Archaeological Research, University of Cambridge, Cambridge, Cambridgeshire, UK

Introduction

Mollusc shells are a common component of many archaeological assemblages. Archaeological mollusc shell accumulations are typically the result of food refuse and may be present within a settlement or as a midden nearby. Mollusc-based artifacts such as shell scrapers and shell beads have also been found in sites from Paleolithic to recent times in many geographic areas. However, some terrestrial mollusc shells may be present in archaeological assemblages even though humans did not actively collect them. Studying the chemistry of shells from archaeological assemblages provides a means to study paleoclimate and paleoenvironmental change that is directly correlated to human activity. Shell chemistry of the final growth increments can also yield information on the seasons in which the shells were harvested. Incorporating climate and seasonality studies within archaeological investigations provides insight on how humans interacted with their environment. Stable oxygen isotope analysis is one of the most common geochemical techniques applied to the analysis of archaeological shells and will be the primary focus of this review.

Definition

The Phylum Mollusca

The Mollusca are a phylum of soft-bodied invertebrates whose bodies are often protected by shells composed of calcium carbonate (either calcite or aragonite). Gastropod and bivalve shells are the most commonly preserved mollusc remains in archaeological sites. Both live in marine, freshwater, and estuarine environments, while gastropods also live in terrestrial environments. The usefulness of mollusc shells as high-resolution environmental archives stems from their shell's incremental growth patterns. Bivalve bodies are encased by a shell consisting of two valves, joined by a hinge. The shells grow by depositing successive increments of calcium carbonate from the umbo to the ventral margin (Fig. 1). Gastropods are encased within a shell, which is often coiled. The shell grows by depositing calcium carbonate growth increments from the apex to the shell lip (Fig. 2).

Molluscs generally precipitate their shells in equilibrium with surrounding ambient environmental conditions. Therefore, the physical and chemical properties of mollusc growth increments record changes in the mollusc's ambient environment during growth. Depending on shell growth rates, high-resolution sampling of these shells can yield environmental information from decadal to

Molluscs (Isotopes): Analyses in Environmental Archaeology, Fig. 1 Idealized morphology of a bivalve shell. The dashed line in (**a**) shows the location of the cross section in (**b**). *DOG* direction of growth

Molluscs (Isotopes): Analyses in Environmental Archaeology, Fig. 2 (**a**) Idealized external morphology of a coiled gastropod shell. The dashed line in (**a**) shows the location of the cross section in (**b**). *DOG* direction of growth

subdaily timescales. Short-lived species can record seasonality and weather extremes, and long-lived species can record decadal- to centennial-scale climatic oscillations.

Molluscs are widely distributed in varied environments and are abundant from the tropics to the poles. This offers the potential for high-resolution time series analyses from almost every geographic region. Many other quaternary environmental proxies such as ice cores and marine sediment cores are limited in their geographical extent and temporal resolution.

Stable Isotopes

Isotopes are atoms of the same chemical element that have the same number of protons (thus the same atomic number) but different numbers of neutrons (thus different atomic masses). Stable isotopes have nuclei that do not decay to form other isotopes. Chemically, all isotopes of the same element behave identically. However, due to their differences in atomic weight, the lighter isotopes have different kinetic properties, causing them to respond at different rates during biological and geochemical processes. In "light" stable isotopes with low atomic masses, the differences in weight between the isotopes are large enough for physical, chemical, and biological processes to cause fractionation whereby the ratio of heavy to light isotopes in the system changes. Oxygen is the most routinely studied stable isotope in archaeological mollusc shells. It has three stable isotopes ^{16}O, ^{17}O, and ^{18}O. The application of oxygen isotope analysis to mollusc shells uses the ratio of ^{16}O to ^{18}O. As the differences in natural abundances of stable isotopes are usually very small, the ratio of heavy to light isotopes is measured with reference to the isotope ratio in an international standard in delta (δ) notation:

$$\delta X = R_{sample} - R_{standard}/R_{standard} - 1 \times 1000$$

X = the heavy isotope and R = the ratio of heavy to light isotope. Measurements are expressed in parts per mil (‰).

If δX is more positive, the sample has a higher ratio of heavy to light isotopes than the standard.

Oxygen Isotopes in Marine Shells

The isotopic composition of marine shell is controlled by water temperature and the isotopic composition of seawater (Kennett and Voorhies 1996). In modern marine environments in mid-to high latitudes, the role of evaporation and rainfall on the overall isotopic composition of seawater is negligible, making sea surface temperature (SST) the primary fractionation factor (Fig. 3). Warmer temperatures enrich ^{16}O relative to ^{18}O, to generate isotopically negative signatures, while cooler temperatures produce positive signatures. In these temperature-dominated systems, $\delta^{18}O$ amplitude (the difference between maximum and minimum isotopic values) records the range of seasonal water temperature fluctuations experienced by a mollusc during growth. The relationship between shell $\delta^{18}O$, water $\delta^{18}O$, and sea surface temperature has been expressed in several equations, so $\delta^{18}O$ in shells can be used to quantitatively reconstruct sea surface temperature regimes of the past (e.g., Dettman et al. 1999). In tropical regions, interannual temperature changes are minimal, so $\delta^{18}O$ of mollusc shells can be used to reconstruct paleo-$\delta^{18}O$ of the water, which is mainly controlled by the amount and composition of rainfall. In such regions, $\delta^{18}O$ can be used to reconstruct precipitation and monsoon regimes.

Oxygen-Stable Isotopes in Terrestrial Molluscs

Oxygen isotope ratios of terrestrial mollusc shells provide a record of continental climatic conditions. In terrestrial shells, the water ingested by the snails principally controls $\delta^{18}O$. However, due to the variability in the oxygen isotope composition of the environmental water consumed by the snails, there is no worldwide correlation between snail shell $\delta^{18}O$ and a single environmental variable (see Zanchetta et al. 2005 for a review of recent studies): in humid regions at lower latitudes, meteoric water or precipitation tends to dominate the signal, while at higher latitudes in more temperate climates, temperature and humidity are the primary variables. Isotopic signatures of land snails from archaeological contexts should be validated in relation to a thorough assessment of isotopic data from live-collected snails of the same or similar species from a similar geographic range and within the expected foraging range of the archaeological site or under experimentally controlled conditions, to provide a baseline for the interpretation of the paleoenvironmental and archaeological data.

Oxygen Isotopes in Estuarine Shells

The mixing between marine and freshwater complicates the interpretation of stable isotope ratios in estuarine shells. In estuarine environments, oxygen isotopes and shell growth may be

Molluscs (Isotopes): Analyses in Environmental Archaeology, Fig. 3 Simple models of seasonal change in shell $\delta^{18}O$ expressed as a deviation from a mean value (X). Temperature is identical in **a**, **b**, and **c**. (**a**): Change in water composition is negligible and temperature is the principal fractionation factor, so the isotope curve closely follows the temperature effect; (**b**): change in water composition is larger. This could be caused by increased summer evaporation or heavier seasonal precipitation; (**c**): higher amplitudes in negative seasonal precipitation combine with temperature to create larger amplitudes in the resultant carbonate isotopic curve (Modified from Dettman and Lohmann 1993)

differently affected by factors such as turbidity, temperature, and salinity variations. In tropical regions, where temperature remains more constant throughout the year, oxygen isotopes from estuarine shells can be used to detect salinity changes from freshwater inputs including changes in paleorainfall/paleomonsoon and seasonal variations in runoff (e.g., Kennett and Voorhies 1996). Outside of the tropics the situation is more complicated as both temperature and salinity variation can differently affect the oxygen isotope record (Fig. 3).

Oxygen Isotopes in Freshwater Shells

Freshwater molluscs present a greater challenge for interpretation than marine molluscs, as the oxygen isotope ratios preserved within shell carbonate preserve evidence of various environmental effects. The $\delta^{18}O$ composition of the ambient freshwater can vary significantly with changes in evaporation and precipitation (e.g., Fritz and Poplawski 1974). In lakes with closed catchments and long water residence time, the local precipitation-evaporation balance is likely to be the controlling parameter on water $\delta^{18}O$ composition. By contrast the controlling parameters in lakes with open catchments and low water residence time are likely to be precipitation $\delta^{18}O$ and/or temperature. In river and lake systems, high evaporation results in more positive $\delta^{18}O$. This has the effect of reducing the seasonal amplitude signal (Fig. 3). River systems may be enriched along their flow paths with isotopically heavy or light rainwater, which will either dampen or heighten the amplitude signatures of the shell (Fig. 3). In order to apply $\delta^{18}O$ analysis for paleoclimatic reconstructions in freshwater systems, a thorough study of modern populations of the proxy species is necessary in order to interpret the paleorecord.

Historical Background

Urey (1947) was the first to reveal that the oxygen isotope composition of biogenic carbonate is temperature dependant, showing that variations in the temperature of the water from which the carbonate was precipitated should lead to predictable variations in the $\delta^{18}O$ ratios of the carbonate. Soon after, Epstein et al. (1951) formulated an empirical paleotemperature equation based on isotopic analyses of molluscs with known growth temperatures.

Season of Collection

The initial focus of stable oxygen isotope analysis on archaeological mollusc shells was on determining the season of shell collection. Shackleton (1973) was the first to recognize that the $\delta^{18}O$ value of the last deposited growth increment reflects the environmental conditions at the time of the animal's death. Season of collection analysis is possible when a primary variable affects the stable isotope composition of the shell. For example, in tropical marine settings, water temperature is fairly constant but $\delta^{18}O$ of the water is affected on a seasonal basis by the $\delta^{18}O$ composition and amount of rainfall. In temperate marine settings, water $\delta^{18}O$ is fairly constant so $\delta^{18}O$ in mollusc shells is primarily influenced by sea surface temperature. Season of collection information is useful for archaeologists because in midden shells, death occurred due to collection by ancient human foragers. Seasonal patterns of shellfish collection bear directly upon interpretations of site use and subsistence behavior, providing important data to aid analyses of foraging practices from the archaeological record. Shellfish season of collection data can be combined with other archaeological data to gain a more complete picture of site use patterns.

These methods have been successfully applied in marine, freshwater, and estuarine environments around the world. In earlier studies, there was debate over the temporal resolution that could be obtained from shell-edge $\delta^{18}O$ values. Killingley (1981) contended that monthly resolution was possible, while Bailey et al. (1983) suggested that only seasonal resolution could be attained. More recently, there has been a growing awareness of the importance of modern validation studies on the proxy species in habitats close to the archaeological study site to understand how factors such as seasonal or ontogenetic variability in growth rates may affect the sample resolution in different environments and latitudes (e.g., Mannino et al. 2003).

The number of samples analyzed in archaeological season of collection studies must balance the need to analyze enough shells per archaeological context to detect meaningful foraging patterns with the need to characterize the pattern of growth to accurately determine season of collection (Mannino et al. 2003). Measuring only the outermost growth increment allows many shells to be characterized using minimal analyses. This strategy works well to identify seasonal extremes (summer and winter); however, it is more difficult to disentangle signatures from shells collected during transitional conditions (autumn and spring). Sequential analyses covering a year or more of shell growth allow more accurate determination of season of shell collection but require many samples from a single shell, so limit the number of individual shells that can be analyzed. Recent studies have suggested a medium between these two extremes whereby the pattern of stable isotope variation of three or four sequential samples inward from the outermost growing edge can accurately illustrate season of death (Mannino et al. 2003).

Paleoclimate

Mollusc shell chemistry provides an archive of climatic and environmental data. Oxygen isotope records from archaeological mollusc shells allow us to study how humans responded to changing climatic regimes in the past. Emiliani et al. (1964) were the first to apply oxygen isotope analyses to archaeological shells to reconstruct paleoclimate. They studied limpets and top shells from Haua Fteah in Libya and Arene Candide in Italy and identified late Quaternary climatic oscillations that correlated with regional Mediterranean climate records.

Most early applications of stable isotope analysis on mollusc shells focused on grinding up whole shells for bulk analyses to obtain average annual climate records (e.g., Mook 1971). Innovations in mass spectrometry and reductions in analysis costs allowed smaller sample sizes to be analyzed, permitting more routine subsampling of shells to obtain series analyses within a single shell.

Recently, there has been a shift toward combining records of shell growth and geochemistry in order to obtain highly detailed time-resolved records of climate and environment. This research comes under the umbrella of sclerochronology,

the study of the physical and chemical variations in the accretionary hard parts of organisms. The time span and resolution that can be obtained for climate records from mollusc shell growth increments depends upon on the sampling method used, the growth rates, and the longevity of the shell. The majority of molluscs exploited by humans have life spans typically less than 10 years. Subsamples from short-lived species produce subseasonally resolved snapshots of the amplitude of the seasonal cycle at the time of shell growth.

In the last decade, highly detailed long-term climate records have been obtained from long-lived bivalve species such as *Arctica islandica* which can live for over 500 years. These slower-growing molluscs can provide annual to decadal records of climate change which may allow identification of climate cycles such as the North Atlantic Oscillation (NAO) as well as long-term climatic oscillations such as Dansgaard/Oeschger cycles throughout the late Pleistocene. Cross-dating techniques, where the individual histories of several shells can be aligned chronologically based on overlaps in their periods of shell growth, allow the reconstruction of longer time series of environmental change. For example, cross-dated archaeological *A. islandica* shells from a Norwegian Stone Age midden have been used to reconstruct a 155-year record of climate related to prehistoric occupations (Helama and Hood 2011).

Shell Sourcing

Another novel application of stable oxygen isotope analyses to archaeological mollusc shells is the use of $\delta^{18}O$ to track foraging ranges. In areas with differential freshwater inputs/salinity regimes but similar temperature ranges, the shape of the seasonal $\delta^{18}O$ curve should be similar, but the absolute values should vary in tandem with salinity (e.g., Andrus and Thompson 2012). Examining the changes in salinity from $\delta^{18}O$ allowed the collection range along the coast to be estimated, allowing more detailed reconstructions of foraging strategies beyond season of collection.

Key Issues/Current Debates

Vital Effects

As with any living creature, molluscan life cycles are complex. An attempt to understand their growth cycles, physiology, and habitat preferences must be made before their shell morphology and geochemistry can be interpreted with confidence (Schöne 2008).

Shell growth may be modulated by internal rhythms or by environmental factors such as temperature extremes, turbidity, storms, or predation. Under favorable ambient environmental conditions, most molluscs precipitate shell material at regular intervals, termed growth increments. Regular periods of slowdown and cessation of growth result in growth lines that interrupt growth increments with periodicities ranging from subdaily to annual. Shell growth may also cease at irregular timescales as the animal aestivates as a result of ambient environmental conditions that exceed the physiological tolerance of the organism such as increased temperature or salinity. In all cases, there are times when ambient environmental conditions are not recorded in shell growth (Schöne 2008).

Shell growth is generally faster during favorable environmental conditions. Therefore, isotopic records taken at regular intervals across a growth band will be biased toward the animal's physiological optimum. Reproduction may slow growth in some species. Mollusc growth rates also vary throughout their life cycles, tending to decrease as the animals age. Variable growth rates will result in time-averaged values for shell carbonate for the periods of slower shell growth. Research on modern populations has shown that the timing and regularity of growth line and growth increment deposition can vary from species to species and sometimes within a single species across different latitudes and environments. These variations need to be understood in order to apply an appropriate sampling methodology to reliably interpret the isotopic records. When a mollusc's growth rate is understood, the time averaging caused by variable growth rates can be corrected for by mathematically weighting each sample (Schöne 2008).

Understanding the habitat preferences of different mollusc species is also crucial to the interpretation of their isotopic signatures. Different species of molluscs that live contemporaneously within a marine, freshwater, or terrestrial context can have different isotopic composition due to differences in water-isotope composition between different microhabitats. Furthermore, in ancient contexts where chronological resolution is more limited, the range in isotope ratios for each species from a single context can be large. Only by analysis of a significant number of species-specific shells from each sampling interval can a true understanding of environmental change be obtained.

Past Water Composition and the Reconstruction of Sea Surface Temperature

Temperature equations (e.g., Dettman et al. 1999) offer the opportunity to reconstruct sea surface temperature from marine shell $\delta^{18}O$ as long as the $\delta^{18}O$ of the seawater where the shell grew is known or can be estimated. Changes in continental ice volume have caused the oxygen isotope ratios in seawater to vary considerably throughout the Quaternary. Mollusc shell $\delta^{18}O$ is a function of both $\delta^{18}O$ of ambient water and temperature. In order to calculate paleotemperatures from shell $\delta^{18}O$, an estimate of paleo $\delta^{18}O$ of seawater must be used. Paleo-seawater $\delta^{18}O$ is most commonly evaluated indirectly through the analysis of $\delta^{18}O$ in fossil carbonates such as planktonic foraminifera or from analysis of resistant organic compounds (alkenones) preserved in sediment cores. Another method is to directly measure $\delta^{18}O$ from pore water extracted from marine sediment cores. Such studies have shown that the last glacial maximum had the highest $\delta^{18}O$ values in the last glacial cycle corresponding with maximum ice sheet extent. This reflects the $\delta^{18}O$ of past bottom waters which can be extrapolated to surface waters. For a more detailed discussion of seawater $\delta^{18}O$ composition, see Rohling (2007).

These methods of paleo-water $\delta^{18}O$ reconstruction yield average values that cannot account for seasonal fluctuations in water composition or for differences in seawater $\delta^{18}O$ that can occur over small geographic ranges. A change in water $\delta^{18}O$ of just 0.5 ‰ (which is the typical seasonal range for many parts of the Mediterranean) can lead to a calculated temperature difference of 2 °C. Applying this to the paleorecord where seawater $\delta^{18}O$ is less well constrained could lead to uncertainties of several degrees in temperature reconstructions. These factors must be borne in mind when using mollusc shell stable isotopes for paleothermometry studies.

Diagenesis

In archaeological mollusc shells, recrystallization of the shell carbonate due to diagenesis will alter the isotopic ratios in the shell carbonate. Diagenesis can occur because of cementation (the addition of abiotic carbonate after death) or because of dissolution and re-precipitation of carbonate within the shell after death. If these phases are analyzed, they do not represent the chemistry of shell growth but the chemistry of the water at the time of diagenesis. Therefore, care must be taken to avoid sampling regions of shells that are diagenetically altered. This can be done in a variety of ways. High-resolution microscopy can be used to directly observe diagenetic alteration in polished section. Sampling strategies or sampling "maps" can then be devised in order to avoid the recrystallized part of the shell. X-ray diffraction can be routinely applied to detect recrystallization in shells originally composed of aragonite that may be altered to the more stable carbonate form of calcite.

Future Directions

As this review shows, stable oxygen isotope analyses on archaeological mollusc shells can yield valuable high-resolution, quantitative environmental archives from the time of shell growth as well as provide information on prehistoric human subsistence strategies. Future research is likely to focus on four key issues:

1. *Modern validation studies*: It is becoming increasingly evident that inter- and intraspecies differences in growth rates, physiology, and environmental responses can cause variations

in the isotopic profiles of mollusc shells. Therefore, before stable isotope analysis is applied to archaeological shells, it is necessary to examine modern populations of the proxy species to understand how isotopic variation in shell carbonate correlates to local environmental conditions. This allows potential isotopic offsets between the environmental signal and the shell carbonate to be identified and, potentially, allows the generation of a more quantitative record of environmental change.

2. *Integration of sclerochronology and cross-dated chronologies*: The integration of detailed studies of shell growth with geochemical sampling enables the generation of high-resolution time-resolved records of environmental change. Cross-dated chronologies can then be constructed to generate continuous, high-resolution records of climate change from archaeological sites.
3. *Combination of stable isotopes with other proxies*: In some mollusc species, element ratios such as Mg/Ca and Sr/Ca serve as proxies for sea surface temperature that are not influenced by the stable isotope composition of ambient water. The combination of independent methods of temperature reconstruction with stable isotope analysis allows the effects of changing water composition from factors other than temperature (such as rainfall) to be disentangled from the isotope record to provide a more robust proxy of temperature. However, the incorporation of strontium and magnesium into mollusc shell carbonate appears to be more variable between and within species, so more work on modern validation of these trace element proxies is necessary before the potential of these integrated records can be realized (e.g., Surge and Walker 2006).
4. *Clumped isotope geochemistry*: This newly emerging field examines the extent to which isotopes such as ^{13}C and ^{18}O bond with or near each other rather than with the surrounding light isotopes. The proportions of ^{13}C–^{18}O bonds in carbonate minerals are sensitive to their growth temperatures, independent of bulk isotopic composition. Therefore, clumped isotopes in ancient carbonate can be used as a quantitative paleotemperature proxy that requires no assumptions about the $\delta^{18}O$ of waters from which carbonates grew (Eiler 2007). The application of clumped isotope analysis to marine and freshwater shells is rapidly expanding; however, the infancy of the techniques means extensive modern validation studies are needed. Furthermore, large sample sizes are required, currently hindering the application of this technique to seasonality studies. The only study to date that has investigated clumped isotopes of modern terrestrial shells showed the results were complicated by snail ecophysiological adaptations such as shell color, morphology, and behavior (Zaarur et al. 2011). Thus, further work is required to disentangle their influence before this technique can be applied to archaeological terrestrial shells.

Molodin, Vyacheslav I.

Mikhail V. Shunkov
Institute of Archaeology and Ethnography, Siberian Branch of the Russian Academy of Sciences, Novosibirsk, Russia

Basic Biographical Information

Vyacheslav Ivanovich Molodin (Fig. 1) was born in 1948. He was a Soviet and Russian archaeologist who specialized in archaeology and the prehistory of Siberia. Molodin was born in Orhovo village of the Brest Region. In 1971, he graduated from the Department of History and Philology at the Novosibirsk State Pedagogical Institute. In 1984, he received his doctorate degree in history.

V.I. Molodin joined the Siberian Branch of the USSR Academy of Sciences in 1971 as

Molodin, Vyacheslav I., Fig. 1 Vyacheslav Ivanovich Molodin

postgraduate student of the Institute of History, Philology, and Philosophy where he was Head of the Division from 1989 to 1991. In 1992, he became Professor and Deputy Director of the Institute of Archaeology and Ethnography of the Siberian Branch of the Russian Academy of Sciences. He was elected a full member of the Russian Academy of Sciences in 1997. From 1997 to 2001, he was Deputy Chairman of the Siberian Branch of the Russian Academy of Sciences. He was the First Deputy Chairman of the Siberian Branch of the Russian Academy of Science from 2001 to 2007.

V.I. Molodin is a member of the Presidium of the Siberian Branch of the Russian Academy of Sciences, as well as the Bureau of the Department of History and Philology of the Russian Academy of Sciences. He is a corresponding member of the German Archaeological Institute.

Major Accomplishments

V.I. Molodin discovered and studied a number of archaeological cultures that existed in Siberia and Central Asia. He has a wide field of scientific interests, such as prehistoric art, Bronze and Iron Age of Siberia, Altai, Mongolia, ethnogenesis, and paleogenetic studies. He developed an ingenious interpretation of the origin of people who inhabited the southern region of Western Siberia from Upper Paleolithic through to the late Middle Ages. He studied the unique and chronologically diverse burial complex of Sopka-2 in the Baraba forest-steppe, as well as the Russian stockaded towns (Ilim, Kazym). He was a Codirector of the international program "Pazyryk" and the Russian-German expedition that discovered and studied a unique settlement of Chicha in Baraba, which dated as far back as the ninth to seventh century BCE. The multidisciplinary research at these sites that was carried out under his direction and actual participation provided fundamentally new scientific knowledge of this region's occupation.

He took part in foreign archaeological research projects in Mongolia, Cuba, Japan, Canada, and Syria. A number of his works were dedicated to the history of science and science studies, as well as church archaeology. He has been awarded state prizes and decorations from Russia as well as foreign countries.

Monasticism in Southern Italy (Fourth to Eleventh Century)

Bozzarello Luca
Department of Humanities, University of Calabria, Arcavacata di Rende, Cosenza, Italy

State of Knowledge and Current Debates

The political division between Byzantines and Longobards had a great influence over the religious and ecclesiastical geography of Mezzogiorno. This division was further marked after 731/732, when the dioceses of the Byzantine provinces of Southern Italy were transferred under the authority of the Patriarchate of Constantinople. As a result, Byzantium limited the influence of Rome aiming to create a national Church united by the common denominator of Greek culture. This operation soon failed in Naples and the city went back to the Roman jurisdiction. On the other hand, the same intent succeeded in Calabria and Sicily where the re-hellenization managed by Byzantium during the sixth to seventh century could reinforce the already strong hellenization coming from Magna Graecia. Those last regions and also some part of Lucania were populated by large communities of hellenophones, thus they were deeply influenced by Greek-Byzantine spiritual models of the Eastern Christian world and by the Greek-rite monasticism too. Instead, Mid-Northern Apulia, Ex-Longobard Northern Calabria (seventh to ninth century) and Campania were located out of these ideal borders. Because these regions were essentially characterized by latinophones, so by Latin monasticism too.

It is possible to identify the Latin monasticism with the St. Benedict Rule only during the Carolingian Age (eighth to ninth century). According to the centralization policy of the Frankish Kings, the operation aimed to homogenize monasticism across Western Europe and it was led by St. Benedict of Aniane. The so-called Pre-Benedictine monasticism (fifth to eighth century) can be described as a colorful mosaic in which the fascination of heremitism (=solitary life) was deeply felt even where *stabilitas loci* had been imposed as the base of the community life (Pricoco 2011: IX–XVII). On the contrary, the Benedictine monasticism was essentially shaped around cenobitism (=communal life), while the influence of heremitism can be collocated in the tenth to eleventh century. The monastic life was organized by the Rule together with some additional *consuetudines* formulated from the seventh century in order to satisfy the new needs emerging when the congregation started to grow.

The Italo-Greek monasticism was essentially characterized by heremitism practiced through the forms of anachoresis (=solitude) as well as hesychia (=two or three people living in different cells). The hagiography has clearly shown how the Italo-Greek monks and saints preferred to live as hermits, according to the Greek-Byzantine spirituality which considered heremitic life as the highest monastic ideal. However, around the tenth to eleventh century, also the Italo-Greek monasteries were reformed through cenobitical life. This change mainly followed imperial and ecclesiastical laws that preferred a cenobitical organization of monasticism since it was considered the best solution in order to avoid anarchy among monks. These laws also allowed the monks to live temporarily as hermits with the approval of their abbots.

Greek-Byzantine monasteries were generally organized through the τυπικά written by their abbots or by the founders. Generally speaking, every monastery for men was independent, but monasteries for women had to be dependent on something or someone (i.e., a male monastery, a bishop, or a laic protector). Scholars largely agree on stating that there was a lack of an official and acknowledged rule across the Byzantine monastic world. However, since 787 St. Basil's Rule seemed to be acknowledged by the ecclesiastical authorities at the Council of Nicaea II, who reformed the double-monasteries settled across the Empire through "*regulam sancti patris nostri Basilii, et secundum praeceptionem eius*" (can. XX = Alberigo et al. 1991: 153–154). In this case, the Conciliar Fathers mentioned the set of Rules written by Basil the Great (329–379) for monks and nuns, which greatly influenced the

development of monasticism. The definition of "Basilian monk" is inappropriate to the historical context here debated since the Basilian order involving all the Greek-rite monks which settled across the Roman Church territory was established only in the sixteenth century by the Papacy.

The issue of vows, which in the current imagination correspond to the beginning of the monastic life, is also quite problematic. This cannot be said for the High Middle Ages' monasticism, nor for Greek-Byzantine and Latin monasticism. Until the twelfth to thirteenth century and sometimes later than that, the Latin monks and nuns often began their monastic life informally, through formulas that avoided mentioning the solemn vows (chastity, poverty, obedience). Instead, the vow of seclusion was imposed to nuns only after the Council of Trento (1545–1563), and it was erroneously considered a way to homogenize with the feminine monasticism at that time.

The female monasticism of the late sixteenth century can be described as a heterogeneous and complicated world. Monasteries for women had been organized by the rules designed for male monasteries, which proved to be unsuitable for nuns. This situation led the nuns to apply informal rules in order to fill up this legislative gap. As a result, each single monastery had become a sort of *unicum* organized by its particular *consuetudines*. The nuns of the Middle Ages usually preferred the cenobitical life, which was not as harsh as heremitism, avoiding experiences characterized by severe physical mortifications. In addition, the cloister often allowed the nuns to preserve their social status and all the privileges related to it. The survival of six Byzantine monasteries' τυπικά (twelfth to fifteenth century), for example, testifies that the nuns living there were divided according to a marked hierarchy which favored the nobles by guaranteeing them easier tasks and comfortable lodging. A marked social difference was also governing the lives of the Byzantine monks, especially inside the main monasteries. Stoudios Monastery, for example, presented a similar scenario. This famous Constantinopolitan monastery was characterized by a strong hierarchy before the more egalitarian reform implemented by St. Theodore the Studite (759–826).

A long tradition of studies has identified St. Antonius as the person who inspired the feminine cenobitical model. According to tradition, it seems that before moving to the desert to live as an hermit, St. Antonius imposed on his sister and to other virgins the cenobitical lifestyle (Ath. *Vita Ant.* III, 1 = Bartelink et al. 1981[3]: 11). This version of facts cannot be accepted anymore thanks to a new and reliable version of his hagiography that states that St. Antonius had given custody of his sister to some pious virgins living at home in order to educate her to virginity (Ath. *Vita Ant.* III, 1 = Baldi 2015: 39). In any case, it has been clearly shown how women played a main role in Christianizing the Roman aristocracy, thanks to the communities of pious virgins or widows which were attested in Rome since the fourth century (Borsari 1963: 9–22; Bozzarello 2017: 158–204; Burgarella 1982: 57–71; Creytens 1965: 45–84; Galatariotou 1988: 283–290; Kazhdan et al. 1991: 269, 1136, 1392–1394; Morini 1999: 53–65; Pelliccia and Rocca 1973–2013: (8) 1420-1428, (10) 552ss.; Penco 1985: 21–173; Pertusi 1965: 382–426; Sansterre 1995: 57–92; Talbot 1985: 1–20).

Status quaestionis and future directions of studies on Medieval monasticism have been exhaustively shown and summarized by the scholars who gathered in Brescia (2000) under the coordination of G. Andenna (2001). In this occasion, the contribution of G. Vitolo (Andenna 2001: 259ss.) must be mentioned. The author, after summarizing the current state of knowledge on Medieval monasticism in Mezzogiorno – mainly reached through the indefatigable work of French and Italian scholars along the second half of the twentieth century – has underlined with appropriate scientific acuity some conceivable future developments of studies by analyzing new and updated sources and repertories.

Centuries Fourth to Sixth

Monasticism started around the second half of the fourth century in Sicily, where it was brought by

monks coming from the Eastern Mediterranean world. Then it spread across all of the Mezzogiorno region toward the end of the following century (Borsari 1963: 23–26). At that time monasticism was already present in Naples. The Monastery of St. Severinus in *Lucullanum*, where the relics of St. Severinus have found shelter, was built around 492–495/496 (Eugippius *Vita sancti Severini* 46, 1–6 = Genovese 2012: 128–131). The monastery was furnished with a *scriptorium* and a rich library by Abbot Eugippio (509–after 533), so becoming an important cultural center and an inspiring model for the creation of the monasteries of *Vivarium* and Monte Cassino.

Contrary to a late tradition (tenth century), it is difficult to be able to identify with certainty St. Gaudiosus, Bishop of Abitinae, as the real founder of the Monastery at Caponapoli. This was the same monastery that had St. Agnellus (532/539–593/600) as abbot (*Lib. Mir. s. Agnelli* prol. = Vuolo 1987: 149–152). The arrival in Naples of St. Gaudiosus is believed to be coeval to the arrival of Quodvultdeus (†453), Bishop of Carthage, who was expelled from Africa in 439 by the Vandal King Gensericus. However the source that documents the Vandal persecution of the African Catholic community does not confirm this version (Victor Vitensis *Historia Pers. Afr. Prov.* I, 5 = CSEL 7 = it. trans. Costanza 1981: 34–35). Nevertheless, all along the Late Antiquity the African culture had deeply influenced Naples, which, at the beginning of the sixth century, could be considered the main Mediterranean archive of St. Augustine's books (Genovese 2012: 13–16).

Vivarium represented an excellent archive of Greek and Latin authors; it had a *scriptorium* and a library. This monastery was founded by Cassiodorus in his family's estate at *Scyllaceum* (Squillace), in Calabria, where he retired in 554. The monastic complex was composed by two monasteries: the former *monasterium Castellense* for hermits, and the latter *monasterium Vivariense* for cenobites. *Vivarium* had its apogee under Cassidorus, followed by a gradual decline until its final downfall attested in the seventh century (Penco 1985: 46–50).

According to the traditional version, Monte Cassino had been founded a few years before by St. Benedict himself (529) after leaving his cave in Subiaco, where he had lived as a hermit for 36 months. Monte Cassino was shortly abandoned by its monks because of the Longobard sack in (577) and it was re-inhabited around 718, when Pope Gregory II (715–731) encouraged Abbot Petronax of Brescia to restore it. In 883 Monte Cassino fell under the Saracens, who demolished the Monastery and slew Abbot Bertharius. Consequently, the monk fled to Teano and then to Capua. Around 950, Monte Cassino was brought back to life by Abbot Aligern (948–985) and a new age of political, economic, and cultural power began (tenth to eleventh century) (Bloch 1986: 4–14; Penco 1985: 131–141).

The Gregorian Age (590–604)

The devastation brought on by the Longobard invasion (568–571) had a great impact over the already depressed economy of Italy. To escape the widespread poverty and a permanent state of war, many monks, ecclesiastics, and lay members of the aristocracy left the peninsular Mezzogiorno and fled to Sicily, the Byzantine region that was spared by the Longobard invasion. According to the traditional historiographical thesis, the main cause of this exodus was the systematic persecution of ecclesiastics and monks by the Longobards. But recently, this thesis has been proved wrong because the episodes of murder should be read as isolated events committed in order to steal precious furnishings or to suppress any opposition from local communities to the military invasion.

Nevertheless, the monasteries were heavily hit by the crisis and suffered from poverty. The crisis was partially alleviated by Roman Church funding. The contributions often made of small monetary subsidies allowed the survival of the monks. Regarding this matter, the relavant donation of 80 lb. of gold (=36 kg) per year, which was divided among the 3000 nuns exiled in Rome (ca. 2 solidi to each nun) by Pope Gregory I, is needed to be mentioned (Greg. Mag. *Reg. Epist.* V, 30 = Recchia 1996b: 160–163). The members of the Roman aristocracy also supported

the monasteries. According to the principles of evergetism, they richly endowed the monasteries that they had previously founded or restored (Borsari 1963: 29–32; Bozzarello 2015: 47–65). Despite all the difficulties, monasticism had planted its roots across the whole Mezzogiorno in the last century of the Late Antiquity.

Centuries Seventh to Eighth

Because of limited sources, little is known of Southern Italy's monasticism in the seventh to eighth century. In any case, a valuable influence over the cultural and religious life at that time had the migrants who came from the Eastern provinces of the Empire and fled to Mezzogiorno and especially to Rome, escaping from the Persian and Arabic invasion of their native lands (seventh century). Despite its small proportions, this migration was relevant because it included members of the social, cultural, and political *élites* of the Byzantine provinces (Borsari 1963: 9–12, 35).

Theodore of Tarsus was one of those migrants. After being nominated Bishop of Canterbury by Pope Vitalianus (668), he moved to England together with the African monk Adrianus, Abbot of Nisidano's Monastery, which was located in the *insula-patrimonium* of Nisida, close to Naples. Once they arrived in England, the two clergymen organized the English Church according to the Roman Church discipline (Beda *Hist. Eccl.* IV, 1 = Lapidge and Chiesa 2008: 328–331), while Adrianus introduced some of the Neapolitan Church's customs to England's Medieval Sanctoral (Cilento 1969: 533–536).

Thanks to a generous number of sources, we have a good knowledge of Naples and its monasteries. *Vitae* of St. Patricia (Acta Sanct. *Aug. V*: 199–219) tells us the life, death, and miracles of the Byzantine virgin. She died near Naples in the late seventh century and her body was miraculously carried to and buried in the male Monastery of Sts. Nicander and Marcian. This is why the place has been known as Monastery of St. Patrizia since the tenth century. Shortly after, her grave attracted an increasing number of virgins and nuns who chose it as a gathering place. The Neapolitan *dux* allowed the women to settle into the Monastery and he moved the monks into the Monastery of St. Sebastian, also known as St. Sebastian *casapicta* in *viridario* or Sts. Theodore and Sebastian. This is the Monastery of Sts. Erma, Sebastian, Cyriac, and Pancras, which had been built before 599 (Kehr 1935: 460; Bozzarello 2017: 96–99).

In 763, the feminine Monastery of Sts. Marcellinus and Peter (Capasso 1881: (1) 262–263) is attested. The monastery fell into decadence and it was restored toward 818–841 by Theodonanda, widow of *Dux* Antimus, who transferred it "*in suo praetorium*," to her palace (Waitz 1878: 428). This has been the only feminine Greek-rite monastery of Naples. It was converted into a Benedictine monastery probably around the eleventh to twelfth century (Luzzati Laganà 1982: 729–752).

Our sources testify that feminine monasticism greatly developed during the eighth century, especially under Bishop Stephen II (767/768–800). The Bishop founded the Monastery of St. Pantaleo, near *balneum Nustriani* (fifth to twelfth century). *Dux* Sergius IV, who organized its life according to the St. Benedict Rule, joined that monastery to the one of Sts. Gregory and Sebastian and turned it into the Monastery of S. Gregorio Armeno (1009). Concerning the foundation of Sts. Gregory and Sebastian, unfortunately, no reliable sources are available. It have been allegedly built around the eighth to ninth century, while the relics of St. Gregory the Illuminator arrived in Naples through Amalfium toward the ninth century, when their *inventio* in Constantinople was recorded. According to a traditional version of the events, the monastery was founded by the Byzantine nuns escaping from the Iconoclastic persecution; however, this version proved to be unreliable since this migration never happened (Bozzarello 2017: 181–190). Bishop Stephen also founded the feminine monasteries of St. Festus and St. Gaudiosus (Waitz 1878: 426). Regardless of its devotional aspect, the operation managed by Stephen can be seen as an efficient choice that allowed the Dukedom's economy to expand by unblocking the Neapolitan construction industry, which had been stagnant for two

centuries. Lastly, two minor monasteries are also attested in Capri and Miseno around 719–731 (Kehr 1935: 429).

Centuries Ninth to Eleventh

In less than a century the whole of Sicily, from Mazara to Taormina (827–902), fell under the rule of the Arab Aghlabites, who were replaced by the Arab Kalbites after 909. Due to the invasion, many monks and civilians from Sicily fled to the peninsular Mezzogiorno, especially to Calabria and Lucania: St. Elias of Enna (823–903/904) moved to Saline, in Southern Calabria; St. Christopher of Collesano and his wife, Kale, together with their sons, St. Sabas and St. Makarios (tenth century), spent their lives living in Merkourion, Latinianon, and Lagonegro, which were between Northern Calabria and Southern Lucania, founding the monasteries of St. Micheal in Merkourion, St. Lawrence in Latinianon, St. Philip at Lagonegro. St. Luke of Armento (or of Demenna), St. Vitale of Castronuovo, St. Leo-Luke of Corleone, and St. Philaret (tenth to eleventh century) also lived a considerable part of their monastic lives in Calabria and Lucania (Borsari 1963: 40–76; Morini 1999: 15–23). The Arab invasion had been an opportunity for the Greek-Byzantine monasticism to carry on its expansion following the colonization of new Southern Italy's provinces led by Byzantium (Burgarella 1982: 57–58).

Siculo-Greek and Calabro-Greek monks preferred to move to the Byzantine lands of Mezzogiorno, mainly because of cultural affinity. They often migrated toward the Northern part of Mezzogiorno, especially Campania, since Calabria became unsafe because of Arabic raids. After leaving Merkourion (981), St. Nilus the Younger (910–1004) fled to Capua, where he was welcomed at the court of the Longobard Prince Pandolfus Ironhead. St. Nilus spent the last part of his life in exile across those Latin lands: he lived with his monastic family in Valleluce (981–996), in *Terra sancti Benedicti*, Serperi (996–1004), near Gaeta, and Grottaferrata (1004), near Rome (*Vita s. Nili* XI-XIV= Giovanelli 1966: 89–110). The itineraries covered by the Italo-Greek saints traced the routes usually followed by the pilgrimage *ad limina apostolorum*: a pilgrimage that passed through territories such as the ex-Byzantine or Longobard Dukedoms of Campania (Campania and South Latium), where hellonophones have been traditionally welcomed (Sansterre 1988: 701–750; Burgarella 2002: 934–988). Besides, the itinerary followed by St. Nilus clearly shows his intention to link the Italo-Greek monasticism to Rome and its papacy rather than to Byzantium (Burgarella 1982: 67–69).

The Norman Conquest

In terms of monasticism, the Normans did not make any major changes. They carried on a gradual Latinization of the conquered territories and they transferred the ex-Byzantine dioceses of Mezzogiorno under the authority of Rome. The Normans, as the Byzantines, gave to the monasteries a strategical function in order to control and manage the territory. This strategy, for example, was applied in Calabria through the establishment of St. Mary at Sant'Eufemia (1062), St. Mary La Matina near San Marco Argentano (1065), and the Holy Trinity at Mileto (1080), all monasteries which were ordered by St. Benedict Rule.

The Normans strategically supported the Greek-rite monasticism by re-founding or richly endowing the main monasteries and by joining the small ones to the great and influential monasteries of Mezzogiorno. The Greek-Byzantine monasticism survived in Calabria and Sicily thanks to a strong hellenization of the population in those regions. This allowed those territories to maintain the Greek language and to become the homeland of the first Humanism initiated by Barlaam of Seminara (1290–1348) and Leonzio Pilato (1310–1365) among others. The Norman occupation and the end of the Byzantine rule did not stop the Italo-Greek monasticism. In fact, the spread of monasticism turned into new forms of organization that carried on its cultural influence deeper

than before. At the same time, however, this phase also corresponds to the beginning of its slow decline due to the end of the relations between Calabria and the East, and especially due to the gradual marginalization suffered by the the Italic hellenophones in the new Kingdom.

Concerning the Normans' support of the Greek-rite monasteries, the main monasteries are worth mentioning. The Monastery of St. Mary of Patir, usually called the New Hodegetria, which is located about 15 km west of Rossano (prov. Cosenza), was founded at the beginning of the twelfth century by the Calabrian monk Bartholomew of Simeri, who had lived as a hermit in the mountains near Rossano. The patron of the monastery was the Admiral Christodoulos, a high official of Greek descent at the Norman court of Sicily who had the title of *protonobelissimos*. Despite the resistance of the Greek Archbishop of Rossano, Nicholas Maleinos, Bartholomew placed the new foundation under the protection of Rome and St. Mary of Patir was granted privileges by Pope Paschal II (1105) as well as by Norman authorities. Throughout the twelfth century St. Mary of Patir had an important Greek *scriptorium*. The monastery functioned until 1806, and its church is still in good condition. Architecture and depictions were inspired by Byzantine art features that evolved into a Norman *koinè* over different areas of Mezzogiorno (Kazhdan et al. 1991: 1596).

Connected to St. Mary of Patir is the Monastery of St. Salvatore *in Lingua Phari* in Messina founded by Luca, pupil of Bartholomew, thanks to the support of King Roger II. The monastery was richly endowed with royal grants and its Abbot, Luca, raised to the ranks of archimandrite (1131). The Archimandritate of St. Salvatore gathered under its authority about 40 Greek-rite monasteries settled between Sicily and Calabria (1133); these monasteries were divided in two types according to the juridical *status* of their dependency.

In 1168, under King William the Good, also the Monastery of Sts. Elias and Anastasius of Carbone in Lucania was raised to archimandritate (Penco 1985: 209–213; Borsari 1963: 89–121).

Campania and Samnium

The Dukedom of Naples was essentially characterized by Latin monasticism, even if it was an heterogenous environment in terms of influences, cultures, rites, and lifestyles. Since the early eleventh century the Neapolitan authorities applied the St. Benedict Rule to homogenize the city monasticism, while the remaining pockets of hermetism had already been eliminated in the late ninth century. Under the rule of the Normans, in the twelfth century, the Latinization process also included a few Greek-rite monasteries in Naples (Luzzati Laganà 1982: 729–731) such as the monasteries of Sts. Sergius and Bacchus and Sts. Marcellinus and Peter. The Monastery of Sts. Sergius and Bachus, which had been united to the Monastery of Sts. Theodore and Sebastian in the tenth century, shared with a few other monasteries the monopoly over the management of agriculture in the Dukedom (Feniello 2011: 135–160). Its monks essentially came from the Neapolitan hinterland, so only a few of them had Greek origins. Also the feminine community of Sts. Marcellinus and Peter, dependent on the Monastery of Sts. Sergius and Bachus, shared the same Neapolitan origins. It is interesting to notice how these nuns maintained some typical Byzantine customs, i.e., the ablutions at baths or the ownership of some personal servants (Bozzarello 2017: 165–169, 197).

The coastal territories belonging to the Longobard Salerno and the ex-Byzantine Amalfium were largely characterized by cave monasteries and sanctuaries. The Sanctuary of St. Michael the Archangel in Olevano sul Tusciano, 30 km southeast of Salerno, was visited in 870 by the Frankish pilgrim monk Bernardus and his two companions. Three years before this visit, on the way to the Holy Land, these pious monks-pilgrims had already been at the Sanctuary of St. Michael the Archangel on Mount Gargano, which had been a popular destination for the whole Middle Age (*Itinerarium Bernardi Monachi Franci* IV-X = Tobler & Moliner: 310–314). Escaping the Arabs, St. Saba of Collesano fled to Atrani (982) and Vietri

(986/988), where he lived in two caves (Borsari 1963: 49, 73). Leo, then Archbishop of Amalfium, built the Monastery of Sts. Cyriac and Giulitta in a "*criptam de supra civitate Atrani*" before 987 (Kehr 1935: 389). The Monastery of the Holy Trinity (=SS. Trinità) at Cava de' Tirreni (prov. Salerno) was founded by Alferius (ca. 1011), a monk from Salerno educated in Cluny. The monastery originated from a cave that had already been occupied by Liutius (post 999–1001), monk-pilgrim of Monte Cassino who came back from the Holy Land in 999–1001 (Kehr 1935: 310–313; *Chronica Monasterii Casinensis* II, 30 = Hofmann 1980: 221). This is the monastery where Dauferius-Desiderius, the great Abbot of Monte Cassino (1058–1087) then Pope Victor III (†1087), started his monastic life.

The Holy Trinity at Cava was involved in the reconfiguration of the whole monasticism of Salerno, operation led by Prince Guaimario III (998–1027) and Prince Guimario IV (1027–1052). The juridical organization of the Holy Trinity was inspired by Cluny's model, especially under Abbot Peter, Alferius' nephew. The monastery was directly subjected to the Holy See, thus it was independent from the political authority of the Bishop of Salerno. Following the example of Cluny, the monastery federated many small Latin and Greek-Byzantine monasteries around itself, in the so-called *Ordo Cavensis*, imposing its power over a very large and homogeneous area (Penco 1985: 185–187).

In Benevento, as well as in Salerno (eighth century), monasticism developed under the great impulse of the Longobards – converted to Christianity in the late seventh century – and it was deeply influenced by Monte Cassino. The same influence fell over the Northern-Eastern Campania (Teano-Capua), Samnium and Picenum (i.e., Chieti), areas of great economic interests since the age of Abbot Bertharius (856–883) (Penco 1985: 131–141). Abbot Bertharius had failed in his attempt to unite the Southern Italy dominions against the Saracens who, coming from Sicily and from the Emirates of Taranto (840–880) and Bari (847–871), were devastating this part of Italy. As a consequence, the Muslims could easily sack Subiaco (829–830), Tivoli, the Roman country (876), and the Neapolitan borders (812–861/865), destroying the Monasteries of St. Modestus in Benevento (ca. 850), S. Vincenzo al Volturno (881), and Monte Cassino (883).

The Monastery of S. Vincenzo had been built around 703 near the source of the river Volturno, in the Dukedom of Benevento, and organized according to St. Benedict Rule. After its destruction, the surviving monks fled to Capua, where they lived until 915, when the Monastery of S. Vincenzo was finally restored. The choice made by the monks was influenced by the coeval relocation from Teano to Capua of the Monte Cassino's community, which was supported by Longobard authorities. In the following decades, S. Vincenzo took care the political and economic reorganization of the monastery. Around 950 its properties were rearranged in the so-called *Terra sancti Vincentii*. Thanks to some privileges granted by popes and emperors, the monastery gained great juridical and spiritual autonomy (tenth to eleventh century). However, after the middle of the eleventh century, S. Vincenzo al Volturno suffered from the great political influences of Monte Cassino, thus it gradually fell into decadence (Kehr 1935: 245–247; Marazzi 2010: 191–200).

The Monastery of Monte Cassino had been restored by Aligernus around 950. As well as S. Vincenzo, also Monte Cassino managed an efficient organization of the *Terra sancti Benedicti*, first under Aligernus and then under Abbots Theobaldus (1022–1035) and Richerius (1038–1055), who improved what was done by their predecessor. This was the apogee of Monte Cassino, which could impose itself as a leader in the political reorganization of Southern Italy. With the capitulation of Bari to the Normans (1071), Byzantium was forced to leave Italy to the Normans, while the Great Schism of 1054 had built the precondition that will lead to the political break between Rome and Byzantium at the time of the Fourth Crusade (1202–1204), when the Westerners sacked and subjugated Constantinople. The Normans, once they had gained the support of the Papacy, initiated the invasion of Mezzogiorno.

Abbot Desiderius was the promoter of the alliance between the Papacy and the Normans and he constantly worked to defend it, especially under the Papacy of Gregory VII (1073–1085), when it seemed to have been almost irreparably compromised. This is why when Desiderius finally accepted the papacy in Capua (1087), he moved to Rome escorted by the Normans, who freed the city from his enemies (Bloch 1986: 84ss.; Cowdrey 1983: 99ss.; Penco 1985: 222–226).

Calabria, Lucania, and Apulia

The process of hellenization reached Calabria at the beginning of the Byzantine dominion, while in Lucania hellenophones' settlements are attested only after the tenth century, after the Byzantine re-conquest (late ninth century) and at the time of the creation of the Theme of Lucania (975–1031/1043), which was located at the border of the new Theme of Calabria. The Italo-Greek Monasticism of Calabria and Lucania mainly flourished in four different areas: Saline, the present area formed by Oppido Mamertina, Palmi and Gioia Tauro in Southern Calabria; Merkourion, which had its center in the hinterland of Scalea and in the Lao River's valley, in Northen Calabria, which was well known for the settlements of St. Fantino the Younger (tenth century) and St. Nilus of Rossano; Latinianon, which was located in the Sinni River's valley, on the Eastern side of Lucania; and the hinterland of Lagonegro (prov. Potenza), in the Western side of Lucania. However, Greek-Byzantine monasteries are also attested in other parts of these regions (i.e., hinterland of Mesiano near Vibo Valentia, Mount Mula near Cassano) and a few have been reported in the Mid-Northen Apulia (Borsari 1963: 40–76; Burgarella 1982: 57–71).

The Italo-Greek monasteries were usually self-sufficient economic centers (von Falkenhausen 1978: 29–55). Their economic reorganization corresponds to the one of the main Latin monasteries in Northern Mezzogiorno – S. Vincenzo al Volturno and Monte Cassino – in terms of chronology and methods. The Italo-Greek monasteries followed the cenobitical rule, but their monks were also allowed to live as hermits for limited periods of time. Concerning the Italo-Greek settlements, it is also worth mentioning the "monk-owners" called kelliotes settled in Oppido (eleventh century), who lived in their own properties and conducted a life of work and prayer. They did not depend on any monasteries but on the local bishop (Burgarella 1982: 57–71).

The Monasticism of Latin Lucania and Apulia is richly documented only from the eleventh century, time of the first Normans' settlement; little information can be gathered from High-Medieval sources. The Normans were generally supportive of Monte Cassino, S. Vincenzo al Volturno, and Cava while extending their religious and political influence over those territories.

Venosa, a native city of the Latin poet Horatius, in Lucania, hosted the Abbey of Holy Trinity. The abbey was allegedly founded or re-founded by Drogon of Hauteville, Lord of Venosa after 1043: the evidence of its existence is not dated earlier than 1044. It gained great power around the end of the eleventh century when it became juridical independent, but it soon fell into decadence. It was then subjected to Cava de' Tirreni (1139), which reformed the monastery and restored its monastic life (Houben 1987: 86–108). The Holy Trinity of Cava further extended its influence on Venosa after having conquered Salento and Southern Apulia (late eleventh century) thanks to the support granted by the Normans of Apulia (Penco 1985: 239).

The development of a monastic life across Mount Gargano, Matera, Avellino, and Nola is particularly related to two influent people who operated during the first half of the eleventh century: St. William of Vercelli (†1142) and St. John of Matera (†1139). St. William founded Montevergine (prov. Avellino), which was born as a monastic community of hermits gathered around him. During a long pilgrimage across Mezzogiorno, St. William, according to his hagiography, established several monasteries in Campania thanks to the support of King Roger II of Sicily, his protector and friend. Montevergine,

however, lived its apogee after St. William's death, when it became a Benedictine monastery. St. John of Matera and St. William had intertwined lives. St. John was the founder of St. Mary of Pulsano on Mount Gargano and of other monasteries in Northen Apulia: all of the monasteries founded by him adopted a severe and elaborated version of the St. Benedict Rule (Penco 1985: 231–239; Fonseca 2008: 75–99; Andenna: 266ss.).

Feminine Monasticism

Since the 1970s, feminine monasticism has acquired its specific autonomy in academic research, after having been partially ignored or superficially studied before. This has allowed us to gain a deeper understanding of the phenomena as long as the studies had not been influenced by political needs. Limited data, however, have been collected on the feminine monasticism of the High-Middle Ages (Andenna 2001: 131–189); hopefully future research will fill this gap.

A few and often not reliable elements are known about high-medieval feminine monasticism of Apulia and Lucania. Only since the Norman age, a relevant network of feminine monasteries developed and flourished; most of them were independent monasteries that followed the St. Benedict Rule (De Leo 1983–1984: 283–324; Fonseca 2008: 11–21, 45–74). Little is known about the Italo-Greek feminine communities: we do not have enough documentation regarding those communities in the Byzantine age and it is only possible to find a small amount of information about them in the saints' hagiographies. More sources have been found concerning the Greek-rite feminine monasteries of Mezzogiorno from the post-Byzantine centuries, when the characteristics of the Italo-Greek monasticism did not change under the authority of Rome (Fonseca 2008: 23–43).

Many feminine monasteries in Mezzogiorno have been documented in the Gregorian age. An officer, an ecclesiastic or a layman, was responsible for the economic management of those monasteries. The officer granted ownership over the monastery and its properties and he was supposed to be its protector, assuring that the monastery received fiscal exemptions (Greg. Mag. *Reg. Epist.* I, 67; IV, 9 = Recchia 1996a: 246–247; Recchia 1996b: 30–35). It is a kind of Byzantine ἔφορος (tenth century), person charged with the administration of feminine Greek-rite monasteries. The presence of an officer (*praeceptor*) is still attested for Neapolitan feminine monasteries – i.e., S. Gregorio Armeno – at the beginning of the eleventh century, while in the following centuries the task to preserve the autonomy of those monasteries was transferred to the main families of the Neapolitan aristocracy (Bozzarello 2017: 181–184).

Mongolia: Archaeological Heritage

Jean-Luc Houle[1] and Jamsranjav Bayarsaikhan[2]
[1]Department of Folk Studies and Anthropology, Western Kentucky University, Bowling Green, KY, USA
[2]Research and Exhibition Department, National Museum of Mongolia, Ulan Bator, Mongolia

Introduction

In Mongolia, as in many other areas of the world, the science of archaeology has its origin in the activities of private collectors and foreign explorers. One of the first archaeological discoveries of great significance for Mongolian heritage dates to 1889, when the Russian explorer N. M. Yadrintsev (Russian Imperial Geographical Society) identified the ruins located on the bank of the Orkhon River as those of Kharkhorin (Karakorum), the capital of the thirteenth-century Mongolian Empire. In the same region and during the following years, two scientific expeditions, one led by the Finnish scholar A. Heikel and the other by Russian archaeologist and explorer V. V. Radlov, examined the eighth-century Turkic *Khoshoo Tsaidam* stelae which bear inscriptions in both Turkic runes and Chinese script. Their work allowed for the translation of early Turkish writing and the discovery of the history of the first Turks – a heritage now shared by both Turkish people and Mongolians. During his expedition, V. V. Radlov also carefully recorded numerous stone stelae carved with depictions of flying deer and other symbols through a collection of drawings, thus calling attention to these now famous anthropomorphic Late Bronze Age/Early Iron

Age (mid-second to mid-first millennium BCE) monuments known as "deer stones." The findings of this expedition were published in the late nineteenth century in a four-volume Atlas of Mongolian antiquities – the first of its kind (Radlov 1892–1899).

Following up on these reports, the Russian archaeologist P. K. Kozlov led an expedition to Mongolia in the 1920s in order to excavate high-profile archaeological sites that included the Mongolian imperial capital of Karakorum (thirteenth century CE), the early Turk sites in *Khoshoo Tsaidam* (seventh–eighth century CE), and Noyon-Uul, an elite cemetery belonging to the Iron Age and Xiongnu period (2nd BCE–2nd CE), the first state-like polity to develop in Mongolia.

While these early expeditions laid the foundation for the type of archaeological work that even now continues to a certain degree in Mongolia, that is, traveling around and excavating intriguing burials and monuments of many periods, they also put Mongolia on the archaeological map and showed the country's incredibly rich archaeological heritage that today continues to attract numerous archaeologists and tourists from various countries worldwide.

Key Issues/Current Debates/Future Directions/Examples

The History of the Protection of Mongolia's Archaeological Record

Early evidence for the "protection" (or preservation) of archaeological sites and artifacts in and around Mongolia is rare but can perhaps be traced to the efforts of Peter the Great in the eighteenth century. Indeed, it is Peter the Great who was the first to recognize the artistic value of the artifacts of the steppe nomads that were being looted from thousands of burials across the Inner Eurasian steppes, and he ordered that the looted art from these burials be bought up and sent to St. Petersburg. Certainly this did little to discourage looting and arguably only encouraged it. Nevertheless, this loot formed the basis of the great collection of the Hermitage Museum.

In Mongolia proper, there are stories that mention that in the past, people were fined with livestock for looting or damaging ancient burials, but it is not until 1921, after the People's Revolution, that state policy was formulated for the first time for the protection of historical and cultural heritage. This was done under the management of the newly founded Institute of Literature and Script (later to become the Institute of Science and finally the Mongolian Academy of Sciences) which had the mandate to register, document, and protect historical and cultural heritage. Early on and in accordance with the new policy, the Institute organized research projects in the modern provinces of Töv, Arkhangai, Bulgan, and Övörkhangai where they began to register and document known historical places of importance, such as the monasteries of Saridagiin khiid, Baruun khuree, and Erdene Zuu, Mongolia's oldest Buddhist monastery. Starting in 1935, Prefectural Research Centers were established in every province of Mongolia, and their work has led to a vast amount of documented information on historical and cultural heritage sites throughout the country. Paradoxically, archaeological expeditions in Mongolia during these early times were all directed by foreign explorers, and no laws existed to keep the excavated artifacts inside Mongolia.

The following decade was marked by the Second World War, and although Japanese archaeologists continued to work in Imperial Japanese-controlled areas of Inner Mongolia and Manchuria, little archaeological work was carried out in Soviet-controlled "Outer" Mongolia. As a result, much of the work done in this region during this period was synthetic in nature.

By the 1950s, Soviet archaeology had arrived in Mongolia, and after the Second World War, the great majority of archaeological work there was done by Soviet archaeologists, though some of it was also carried out by European and Japanese scholars. Of particular importance during this time were the archaeological expeditions at Karakorum led by Russian scholar S. V. Kiselev. These excavations were the training ground for the first generation of native Mongolian archaeologists lead by Kh. Perlee and Ts. Dorjsuren. Shortly

after, both Perlee and Dorjsuren would go on to resume excavations at the Xiongnu period Noyon-Uul cemetery – the first Mongolian-led archaeological expedition.

This period also marked another milestone in cultural heritage legislation. In 1941, the Presidium of the State Baga Khural (State Assembly) adopted new rules for the protection, preservation, and regulation of historical and cultural heritage, the most important one being that henceforth monuments and objects of historical and cultural heritage found on the Mongolian territory were recognized as national property. Despite this, no law was in effect to keep the archaeological materials inside the country. Yet during this time and under the administration of Kh. Perlee (Mongolian Academy of Sciences), a database was developed in order to record the results of archaeological excavations. This first "handwritten" database is kept at the Institute of Archaeology, Mongolian Academy of Sciences. For the next 30 years, no changes were made to the legislation regarding the protection of historical and cultural heritage, although in 1964 Mongolia did sign the international UNESCO Convention for the protection of cultural property in the event of armed conflict that was previously adopted at The Hague (Netherlands) in 1954.

It is not until 1970 that the State Assembly adopted a new law for the protection of cultural properties within the Mongolian People's Republic. Although only in effect in its original form until 1994, this new legislation now comprehensively and systematically included all activities related to research, analysis, conservation, preservation, promotion, and dissemination of historical and cultural heritage within Mongolia. This led to a heightened awareness of national heritage and to a period when the Mongolian government commissioned numerous projects that aimed at discovering, registering, and conserving works of historical and cultural significance. Due to these efforts, especially in regard to the dissemination of the information, the outside world gradually started to get to know about Mongolia's unique cultural heritage.

The 1990s marked a turn not only in the political sphere with the fall of the Soviet Union and Mongolia's transition toward democracy but also in cultural heritage protection. In 1994, the State Assembly adopted a Historical Monuments Act which made the vandalism of sites illegal. Unfortunately, the responsibility of enforcing the law and protecting the monuments was left to local residents alone, and though means to finance this new law were included in the legislation – including investment from the state and income from tourism – no moneys were ever made available. Consequently, the looting and destruction of sites continued. Nonetheless, following the guidelines of this Act, the Ministry of Culture established a Center for Cultural Heritage which instituted a unified cultural heritage registration database in 1996. This registry complies with ICOMOS' principles for the recording of monuments and sites as it was ratified by the 11th ICOMOS General Assembly in 1996.

After several amendments made to the 1994 Historical Monuments Act and under the provisions of the 2001 Law on Protecting Cultural Heritage of Mongolia, hundreds of historical and archaeological sites are now officially under the protection of either the Mongolian state, individual provinces (*aimags*), or rural districts (*sums*). In reality, however, there are little differences between these levels of "protection" beyond prestige. Indeed, the level of recognition depends on the historical or cultural significance of a site or monument. But even the ones on the state list do not receive more protection than the ones on the other lists. It is merely more difficult to get permits to conduct archaeological work at these sites. None receive financial support from the government for their protection or conservation, and protecting these sites consists essentially in protecting the natural aspects around the sites and restricting or banning mining and development in the inscribed areas. Some of the most significant sites on the state list of protected monuments are listed and briefly described in Box 1.

Among the most important sites in terms of Mongolian heritage, however, are those located in the Orkhon Valley in central Mongolia. In 2004, the UNESCO World Heritage Committee inscribed the Orkhon Valley Cultural Landscape on the World Heritage List, one of only two inscribed sites to date in Mongolia. The protected region covers an area of about 122 ha and is rich with a diversity of prehistoric and historic sites, including Khar Balgas (the capital of the Uyghur Khanate, which ruled Mongolia from CE 745–854), Karakorum (the great Mongol capital, which was established in 1235 by Chinggis [Genghis] Khan's successor and third son Ögödei Khan), and the sixteenth-century Erdene Zuu monastery (Mongolia's oldest Buddhist monastery, founded in 1586 by Ablai Khan). Interestingly, the colossal grey brick walls that enclose the monastery's compound were constructed using the stones and bricks from the nearby ruined capital of Karakorum City. In collaboration with the Mongolian government, a new museum sponsored by the Japanese government opened its doors in 2010. In addition to exhibiting the findings of various archaeological projects at Karakorum, including those from the 2000–2004 German-Mongolian excavations, the museum's mission is said to include research as well as the collection and preservation of artifacts.

The only other sites on UNESCO's World Heritage List were just added in 2011 after a sustained effort by renowned art historian Esther Jacobson-Tepfer (University of Oregon) and are subsumed under the Petroglyphic Complexes of the Mongolian Altai. These Complexes consist of three rock art sites which display large concentrations of well-preserved petroglyphs and funerary monuments that range in date from the early-mid-Holocene (c. 11,000–6,000 years BP) to the Turkic period (7th–8th c. CE). The three rock art sites, *Tsagaan Salaa-Baga Oigor* (*Ulaankhus sum*), *Upper Tsagaan Gol* (rock arts of Shiveet Mountain), and *Aral Tolgoi* (*Tsengel sum*, *Bayan-Ulgii*), are also included on the list of historical and cultural properties that are under state protection.

Box 1Significant Sites Inscribed on the State List of Protected Monuments

Gandantegchinlen Monastery (1840–)

Located northwest of Ulaanbaatar's city center, this monastery is the center of Mongolian Buddhism and houses the Mongolian Buddhist University. It is one of few monasteries that survived the 1930s Stalinist purges when most monasteries were destroyed. It houses a large library of rare books and manuscripts in Mongolian and Tibetan on Buddhist philosophy, astrology, and medicine.

Bogd Khan's Green Palace (or "Winter Palace")

Located on the south side of Ulaanbaatar, this European-style building was built in 1905 by Tsar Nicholas II of Russia for Öndör Gegeen ("High Lama"), Mongolia's eighth and last religious and political leader. It is now a museum.

Bilge Kagan and Kül Tegin stelae

These are two of the most famous of Mongolia's stone stelae. They are both located near Kharkhorin (Karakorum) City in the Orkhon Valley, date from 732 CE, and bear inscriptions in both Turkic runes and Chinese script. Both are also dedicated to the Turkish Khans who ruled Mongolia between the sixth and eighth centuries. The stelae have been taken under preservation by the Turkish International Cooperation and Development Agency (TIKA) through the construction of a local museum. The National Museum of Mongolia (in Ulaanbaatar) exhibits a copy of the stelae.

Uushgiin Uwur Deer Stone Complex

Located in Khovsgol province, the Uushgiin Uwur Deer Stone Complex includes 18 deer stones. These, as others across western and north-central Mongolia, are associated with sacrificial offerings of horses whose east-facing heads, cervical

(continued)

Box 1Significant Sites Inscribed on the State List of Protected Monuments (continued)

vertebrae, and hooves are buried in a shallow pit below a small circular mound of stones. Often accompanied by stone burial mounds known as *khirigsuurs*, these monuments together form what increasingly seems to be closely related components of a single Late Bronze Age ceremonial complex. The joint Mongolian-Smithsonian Deer Stone Project has carefully documented the Khovsgol deer stones, which includes for the first time three-dimensional records of individual monuments (Fitzhugh 2005).

Xiongnu Period Sites

All important Xiongnu period sites are on the state list, including the elite cemeteries Tsaram (southern Buryatia), Gol Mod 1 and 2 and Noyon-Uul (north-central Mongolia), Takhiltyn Khotgor (western Mongolia), and Duurlig Nars and Bor Bulag (eastern Mongolia).

Conclusion: Current Problems and Prospects

Despite the 1994 Historical Monuments Act, there is unfortunately still very little enforcement of the laws nor a structured monitoring system in place to prevent theft or destruction at important heritage sites. A major problem in establishing a national level protection plan stems not only from a lack of coordination at the government level but from the more basic problem of having a territory the size of Mongolia and only some 50 professional archaeologists to manage the vast numbers of antiquities and sites. Accordingly, many historical and cultural sites continue to be destroyed by human activity and natural decay. For example, physical damage to some monuments has recently increased due to certain worshiping practices. This includes the spraying of milk and butter oil on ancient stone stelae and the practice of wrapping the stones with silk scarves (*khadag*) – a practice which traps in moisture and thus accelerates decay.

More significantly, economic changes in Mongolia in the past 20 years have caused more families to fall below the poverty level, and one way some herders have found to supplement their income has been to sell looted antiquities to tourists. Fortunately, there is an increasing awareness of the problems related to the issue of cultural heritage protection in Mongolia, and a number of national and international efforts for protecting, preserving, and even restoring monuments are in progress.

For example, shepherded by the second author, the recently established Mongolian Tangible Heritage Association (NGO) works at protecting the tangible heritage of Mongolia by working to improve legislation linked to cultural heritage, by communicating and cooperating with international organizations that have the same aims, and by implementing concrete comprehensive projects that strive to protect Mongolia's tangible heritage. One such recent project was the restoration of the *Jargalantiin Am* deer stone site in Khanuy Valley, Arkhangai *aimag*, one of Mongolia's most important deer stone sites yet discovered and soon to be included on the provincial (*aimag*) list of protected sites (Turbat et al. 2011).

Detailed inventory work by Esther Jacobson-Tepfer and colleagues in the Altai region of western Mongolia, as well as work by the members of the Smithsonian Institution's Deer Stone Project, has also done much for digitally recording (and thus preserving) important data regarding rock art sites and other archaeological monuments.

In addition, the arrival of large western mining companies in Mongolia has recently spurred the development of a cultural resource management (CRM) arm in the Institute of Archaeology, in the National Museum of Mongolia, at the National University of Mongolia, at the University of Science and Technology, and at the International Institute of Nomadic Culture. This promises systematic, funded fieldwork and published reports on the archaeology from areas threatened by mining.

International collaborative research projects and support from foreign governments are also playing an important role in cultural heritage preservation. To be sure, to date almost all financial support for Mongolian heritage comes from foreign sources. For example, over the past decade alone, the USA has provided over US $800,000 in nine separate grants under the Ambassador's Fund for Cultural Preservation. As mentioned earlier, the building of museums in the ancient capital city of Karakorum, which house artifacts of national significance, has been sponsored by the Turkish and Japanese governments.

That being said, all these efforts will be for naught without a change in local public attitude toward archaeology and cultural heritage. The National Museum of Mongolia in Ulaanbaatar as well as local provincial museums is playing important roles in this regard by promoting public awareness. However, increasing economic hardship among herders promises to be the biggest challenge to overcome. Clearly, the support of the local population is essential for the protection of cultural heritage, especially given the vastness of the country and the lack of available human and financial resources.

Introduction

The Paleolithic of Mongolia has been investigated for about a century since the original proposition of a Central Asian origin of humans by H. F. Osborn (e.g., 1927). Between 1920 and 1930, explorer R. C. Andrews conducted surveys in the Gobi and the Gobi-Altai regions but failed to find evidence supporting this hypothesis. The first convincing evidence for Pleistocene human occupation is represented by artifacts collected along the Saikhan and Arts Bogd Uul ranges and nearby Orog Nuur Lake. Archaeologist N. C. Nelson, however, could not find anything comparable to the West European Lower Paleolithic (Fairservis 1993). Between 1927 and 1935, the Chinese-Swedish expedition led by explorer S. A. Hedin investigated Mongolia and Northern China. The team's archaeologist F. Bergmann was not more successful in finding grounds for Osborn's hypothesis. In 1949, during a Soviet-Mongolian scientific expedition, A. P. Okladnikov, assisted by N. Ser-Ojav, discovered the Paleolithic site of Molty-nam along the left bank of the Orkhon River, close by the town of Karkhorin (Okladnikov 1978). Other Paleolithic localities were found in the Tola Valley, in the vicinity of Ulaanbaatar, and nearby Mt. Bogdoul. Upper Paleolithic artifacts were reported near the city of Darkhan and along the Khalkin-Gol River. In the 1950s, Ser-Ojav and Mongolian scholars such

as H. Perlee and Ts. Dorsjuren surveyed almost the entire Mongolian territory (Gunchinsuren 2009). They reported finds attributed to the Paleolithic period in the Gobi-Altai region. Russian geologists N. Florensov and N. Skvortsov identified flint quarries with Levallois-Mousterian artifacts in the southern and in the southeastern part of Mongolia. During the 1960s, the cooperation between Okladnikov and Mongolian scholars continued, notably with the excavation of the Molty-nam site (Fig. 1).

In 1969–1970, further surveys in eastern Mongolia also led to the description of "pre-Upper Paleolithic" artifacts, such as pebble tools, from the vicinity of the town of Sainshand (Okladnikov 1978). Starting from 1983, a Soviet-Mongolian expedition directed by A. P. Derevianko surveyed the Valley of the great lakes in western Mongolia, the central and eastern Gobi-Altai district, and the southern ranges of the Khangai Mountains (Derevianko et al. 2000b). Excavations at Orkhon-1 and Orkhon-7 sites, Orog Nuur 1 and 2, or Nariyn Gol-1–17 were carried out in the framework of this project. Starting from 1995, J. W. Olsen, A. P. Derevianko, and D. Tseveendorj initiated the Joint Mongolian--Russian-American Archaeological Expeditions (JMRAAE). This program includes excavations of newly discovered sites in Northern Mongolia and in the Central Gobi region, but also intends to generate chronometric data (Gladyshev et al. 2010a). Numerous sites were documented in the Ikh Tulberiin Gol Valley, and excavations were conducted at the Tolbor 4 site, but also at Tolbor 15. In Central Gobi, cave sites such as Tsagaan-Agui and Chikhen-Agui were excavated by an international team (Derevianko et al. 2004). Between 1999 and 2001, the Dörölj 1 site, located along the Eg River, was excavated by a joint Mongolian-French team led by J. Jaubert (Bertran et al. 2003; Jaubert et al. 2004). This project followed a survey of Paleolithic locations in the Hovd province and a geological reassessment of the Molty-nam geological section. A fossil uncovered at Salkhit, northeast Mongolia, was recognized in 2006 as a human skullcap (Coppens et al. 2008). Since 2010, ongoing study has been devoted to both the morphology of the skull and its geological and chronological position. Furthermore, archaeological surveys are being conducted by J. Braga, N. Teyssandier, D. Tseveendorj, and B. Gunchinsuren in the vicinity of the find. In Khentii province, geoarchaeological researches were recently conducted by M. Izuho and B. Tsogtbaatar at the Khanzat-1 locality and by S. Yi at the site of Rashaan Khad. In 2011, an international team started excavations at the newly discovered site of Tolbor 16, in Bulgan province, under the direction of N. Zwyns,

Mongolia: Paleolithic, Fig. 1 Map with the main stratified sites and human remains mentioned in the text (Modified after NASA World Wind)

S. Gladyshev, and B. Gunchinsuren. All in all, almost a century of research has brought substantial advances in the understanding of Mongolian Paleolithic, and recent projects have yielded promising results that contribute to these efforts.

Definition

The Paleolithic of Mongolia can be defined based on the Eurasian system of division into three main periods: the Lower, Middle, and Upper Paleolithic. The Lower Paleolithic corresponds to the first human occupation of Mongolia and is not yet dated. The Middle Paleolithic would start at the end of the Middle Pleistocene and last until c. 50 ka. The Upper Paleolithic covers a time range from c. 50 ka to the end of the Pleistocene.

Key Issues/Current Debates

The Lower Paleolithic

Previous researches have underlined the difficulty in attributing archaeological material to this period as it often occurs as surface or redeposited assemblages. The presence of a Lower Paleolithic human occupation is inferred from typo-technological descriptions of lithic assemblages, or on the basis of taphonomic features such as the patina. In southwestern Mongolia, the Kholobolchi assemblage was collected during Andrews's expedition (American Natural History Museum collection). It includes moderately patinated artifacts such as choppers and chopping tools, adzes, and flakes, made of metamorphic rocks (quartzite, basanite). The assemblage of Ulan Nor is said to be more evolved and was produced on red jasper (Fairservis 1993). In Eastern Mongolia, Okladnikov pointed out the archaic typological aspects of surface collections from the Sainshand area (Okladnikov 1978). The described pebble implements are associated with vast basins formerly covered by lakes. Okladnikov considered these artifacts as "very similar to the most ancient pebble implements found in Africa and Western Europe." Chopping tools, blocks with bifacially shaped working edges, are reported and have been referred to as "proto-hand axes" or "biface preforms." The latter type of artifact is reported westward, in south-central Mongolia, nearby the city of Dalanzadgad and on the western edge of the Gobi-Altai area. Split pebbles, choppers, and chopping tools were collected from Bayan-Ölgii, the westernmost province of Mongolia, and their ancient age is inferred from the observed patina. Okladnikov (1978) acknowledged, however, that pebble tools occur in various chronological contexts in Siberia. More recently, researches at Tsagaan-Agui Cave, in the Gobi-Altai province, have yielded assemblages of archaic aspect in the lower part of the sequence (Derevianko et al. 2000a). The tool kit includes biface preforms and "spurs," elements that also occur in the surface collections of the Flint Valley (Derevianko et al. 2002). More surprising are the reported "proto-wedge-shaped cores" with bladelet removals and the flake cores similar to the preferential Levallois method. This material has been compared with other assemblages from Lake Balkhash (eastern Kazakhstan) and interpreted as belonging to "Levallois-Acheulean-like" industries. They are tentatively interpreted as evidence for population movements from west to east. The age of human occupation is inferred from radio-thermo-luminescence (RTL) dates derived from layers 5–12 and ranges between 170 and 650 ka. Although an inversion of polarity was detected in the entrance (layer 11) and first interpreted as the Upper Matuyama chron (Derevianko et al. 2000a), the RTL dates are considered much too old. In fact, they could reflect the high residual signals of unbleached sediment particles (Derevianko et al. 2004).

In sum, the cultural and/or chronological attributions of the so-called Lower Paleolithic assemblages in Mongolia remain unclear due to the current lack of contextual data. Therefore, pending new discoveries, the timing and the nature of the earliest human occupation in this region remain uncertain.

The Middle Paleolithic

The recognition of the Middle Paleolithic occupations of Mongolia is complicated by the lack of contextual data available, numerous assemblages

being surface collections. In other words, the problems of definition mentioned for earlier periods also apply to the Middle Paleolithic. As is often the case in Asia, archaic technological features are relatively ubiquitous, and a well-pronounced flake technology occurs in assemblages from various periods. In the absence of a chronological framework, the boundary between the Lower and Middle Paleolithic remains unclear. According to some authors, Levallois technology first occurs among the Acheulean-like assemblages that would later develop toward a Mousterian techno-complex (Derevianko et al. 2000a). The earliest evidence of Levallois-like technology has been reported in the lower part of the section at Tsagaan-Agui, but Middle Paleolithic assemblages are better attested in the middle part of the section starting from 90 to 70 ka. Together with Orog Nuur I-II and Argalant I, it corresponds to the Orog Nuur Levallois-Mousterian variant (Derevianko et al. 2004), also known by the surface assemblages from the Valley of Lakes. The latter are not dated and their chronological assignment is based on their degree of weathering, their patina, and their techno-typological features. The undated material from the localities of Hoit Tsenker gol and Tzakhiriin uzuur, in Western Mongolia, may also represent evidence for Levallois technology (Jaubert et al. 1997). In fact, Mousterian as found in Central Asia (e.g., Teshik-Tash) or the Altai "Sibiryachikha" Mousterian is still unknown in Mongolia. Stronger evidence of Levallois-like technology is documented in Northern Mongolia and is associated with the earliest manifestation of blade production. These assemblages illustrate the shift from the Middle to Upper Paleolithic.

The Upper Paleolithic

The beginning of the Upper Paleolithic in Mongolia is characterized by the spread of blade-based lithic assemblages. The earliest examples have been reported from Northern Mongolia. Using material from recent excavations and newly obtained chronometric data, S. Gladyshev and colleagues have proposed a periodization of the Upper Paleolithic into three main stages (Gladyshev et al. 2010a) (Fig. 2).

The oldest occurrence of Upper Paleolithic technology comes from Horizons 5 and 6 at Tolbor 4. The blade-based assemblages are characterized by the production of massive-to-medium blades with parallel ridges and facetted or plane platforms. Lithic reduction is mainly represented by bidirectional cores with two opposed platforms, with alternate use of the broad and narrow faces, or by genuine volumetric cores. Crested blanks are detached to initialize reduction or to reshape the core convexities. These technical blanks, as well as slabs displaying a specific morphology, are transformed into burin cores for the production of small blades and bladelets. Convergent blades with Levallois morphology are produced in the framework of the

Mongolia: Paleolithic, Fig. 2 View of the Tolbor Valley. (Photo credit N. Zwyns)

blade reduction, but smaller size points also occur. The radiocarbon dates available for these two levels seem to indicate an age c. 40–37 kyr uncal. BP (Gladyshev et al. 2010a). These assemblages are chronologically and technologically similar to the Initial Upper Paleolithic as defined in the Siberian Altai (Zwyns 2012) (Fig. 3).

The second chronological stage includes Early Upper Paleolithic assemblages from Tolbor 15, Horizons 5–7, Tolbor 4, Dörölj 1, Chikhen-Agui Rockshelter, and Chikhen 2 (Gladyshev et al. 2012). Reconstructed reduction sequences mainly show production of large-to-medium size blades from unidirectional volumetric blade cores. The blanks show an increase in plain platforms prepared by thin abrasion, likely representing the generalization of soft-hammer use. Burin-core technology is absent; however, a tendency to "microlithization" is expressed by the production of bladelets detached from truncated-facetted or narrow-faced cores. The occasional occurrence of elements such as carinated end scrapers and bladelets with marginal retouch is considered as a typical feature for these assemblages dated between 33 and 26 ka uncal BP. Orkhon-1 (units 1) and Orkhon-7 (unit 1) seem to represent the latest assemblage of this chronological group, dated to between 26 and 23 kyr uncal. BP.

The third chronological group is known only from the middle Selenga Valley with the Horizons 3 and 4 from Tolbor 15 (Gladyshev et al. 2010b). Bladelets are produced by percussion and by pressure flaking from micro-cores of fine-grained raw material. The only date available for this group indicates an age c. 15–14 ka uncal. BP and as such represents the only Paleolithic occupation directly dated post-Late Glacial Maximum (Fig. 4).

Human Fossils

The skullcap from the Salkhit Valley, in northeast Mongolia, is so far the only Pleistocene human fossil found in Mongolia. It consists of a frontal with partial nasals and parietal bones of unclear taxonomic affiliation. Initially referred to as *Mongolanthropus* (Tseveendorj et al. 2006), its relatively robust morphology was also described as a combination of *Homo erectus*, *Homo neanderthalensis*, and Asian archaic *Homo sapiens* features (Coppens et al. 2008). No archaeological material was found associated with the fossil, and although the fauna found in the vicinity would indicate a Pleistocene age, numerous questions remain regarding the context of the find. The reassessment of the geological context, the direct dating, and detailed morphological analysis of the fossil being conducted by J. Braga, D. Tseveendorj, and B. Gunchinsuren are currently ongoing.

Future Directions

Numerous questions remain concerning the timing of the earliest peopling of Mongolia. Although the presence of *Homo erectus* in the region is assumed, in situ evidence of Lower

Mongolia: Paleolithic, Fig. 4 Periodization of the Mongolian Upper Paleolithic based on chronometric data. (Modified after Gladyshev et al. 2010)

Paleolithic occupations is rather elusive, and no systematic production of bifaces of Acheulean type is documented. Current understanding of Middle Paleolithic human occupation of Mongolia reflects similar problems. Levallois technology is clearly documented in surface collections but is far less represented by in situ examples. The origin and the processes of development of this technology are still poorly understood, and the makers of the Middle Paleolithic assemblages are still unknown. In southern Siberia, the recent sequencing of a previously unknown genome seemingly indicates that a population of archaic hominins, known as the Denisovans, occupied a vast territory ranging from the Siberian Altai to Australia until the Late Pleistocene. Mongolia overlaps with the geographical range of the Denisovans and therefore appears to be a key area for our understanding of Northeast Asia. So far, not much is known about the morphology, the timing of emergence, and the material culture of these enigmatic hominins. The earliest appearance of blade assemblages and the subsequent spread of microblade technology could suggest cultural contacts with the Altai and probably with northern China during a period that corresponds to the first appearance of modern humans in Southeast Asia. Furthermore, the appearance and development of microblades produced by pressure flaking also underline the relevance of Mongolia in the debate concerning the peopling of America (Gladyshev et al. 2010b).

Addressing key issues regarding the role played by exogenous cultural influences and environmental factors in the development of the Mongolian Paleolithic requires the acquisition of an extensive data set. Intensive dating programs such as the one provided by the JMRAAE project stand as the first breakthrough in the Paleolithic periodization of Mongolia (Gladyshev et al. 2010a) and are examples of the kind of efforts that will be pursued in forthcoming years. Beyond historico-cultural issues are numerous behavioral, ecological, and environmental questions that the results of ongoing and future field projects will help to address.
